principal factors governing the present state of industrial uncertainty.

An increased pig iron demand, however, stands out as the most favorable factor in the whole business situation.

The average rate paid common laborers (pick and shovel men) in construction operations has remained at 54c. during the last six months; the June rate being 53c. per hr., according to *Engineering News-Record* figures. Local conditions are as follows:

Atlanta—Small demand for building trades mechanics within city; construction active in outlying districts.

Baltimore—Conditions normal in building trades with possible exception

of structural iron workers and common laborers.

Birmingham—Structural iron workers now receiving maximum of \$1 per hr., against \$1.25 formerly. Men employed on municipal jobs being paid the lower rate.

Boston—Building trades mechanics plentiful; all classes. Carpenters, however, receive maximum rate of \$1.10, compared with \$1.05 per hr., on residential construction work.

Cincinnati—New carpenters' union formed under auspices of Building Trades Council, due to dispute between carpenters and sheet metal workers. Wage scale still \$1.05 per hr.

CURRENT BUILDING TRADES WAGE RATES PER HOUR

Dallas—Excessive demand for bricklayers and carpenters; ample supply of other trades.

Detroit—Release of men from manufacturing plants has supplied needed labor for construction work. No shortage in any of the building trades.

Kansas City—Carpenters advanced 12½c. per hr. since last month. Minimum rate for common laborers 40c. as against 35c. per hr., formerly.

Montreal—Ample supply of all crafts.

New York—The old Building Trades Council with a membership of about 100,000 men, demand a wage increase of \$1 per day for a period of two years,

beginning Jan. 1. Present base pay of \$9 per day, with a bonus of \$1, making \$10, would be advanced to a base pay of \$11 should this demand become effective.

Philadelphia—Sufficient building trades mechanics to meet all demands. Surplus of common laborers. Maximum rate for hoisting engineers \$1.13½ as compared with \$1.02½ per hr. formerly.

Pittsburgh—Building labor plentiful; demand "eased off" during last few weeks.

St. Louis—No change in present building trades wage schedule. Lathers have served notice that they will ask

\$15 for an 8-hr. day on March 1, the largest wage ever reached in St. Louis under a contract. Bricklayers and plasterers now receive \$1.75 per hr. with some talk of asking \$2 with a 5-day week. Electrical workers, carpenters, elevator constructors, plumbers and steam fitters get \$1.50 per hr., with individual workers being paid bonuses above that amount.

San Francisco—Building trades well employed.

Seattle—Plasterers on strike for \$10 @ \$12 per 8-hr. day. Two large jobs, however, are paying \$11 per day; most other jobs non-union.

Monthly Prices of Construction Materials

Ups and Downs of the Market

Pig Iron—November iron sales reached million ton mark. Present low iron prices may rise to meet steel or latter may tend downward in the direction of iron quotations. No. 2 foundry iron, \$22 at Birmingham, against \$24 per ton one year ago.

Railway Supplies—Minimum on light rails up \$2 per ton at Pittsburgh mill, during month; present price \$2@5 per ton above year ago. Standard spikes down in San Francisco; track bolts lower at Pittsburgh mill.

Pipe—Wrought pipe demand largely confined to butt weld sizes in small tonnages. April 19 basing card still in effect at Pittsburgh. Cast-iron pipe slightly lower than month ago in New York; over \$7 per ton higher than one year ago. Sewer-pipe and clay drain tile firm at present levels.

Road and Paving Materials—Downward trend in Mexican asphalt in Boston and Atlanta. Road oils unchanged. Average daily crude oil production declining.

Sand, Gravel and Crushed Stone—Sand down about 5c. per cu. yd. in Cincinnati and Atlanta. Gravel declined

10c. per ton in Atlanta and rose 25c. per cu. yd. in New York, during month. Crushed stone down 10c. per ton in Atlanta.

Lime—Hydrated lime declined in Boston and Atlanta; lump lime in Atlanta, Dallas and Detroit. Common lump, however, advanced 20c. per bbl. in Boston.

Cement—Reduction of 10c. to 25c. per bbl. at various mills throughout the country. Drop reflected in dealers quotations. Owing to change in freight rates in Illinois and Wisconsin, effective Nov. 24, price at Peoria, dropped from \$2.41 to \$2.27 and at Milwaukee from \$2.37 to \$2.25 per bbl. A voluntary downward adjustment in mill prices brought the delivered price, f.o.b. Detroit, to contractors, to a basis of \$2.37, against \$2.48 last month. These reductions while in part seasonal, were also made to stimulate renewed interest in winter construction.

Structural Steel—Steel bars continue firm at \$2.40 per 100 lb., Pittsburgh. Shapes and plates have been quoted as low as \$2.40 for large tonnages; small lots or specified deliveries, however,

bringing a minimum of \$2.50 per 100 lb.

Brick and Hollow Tile—Common brick advanced 50c. in San Francisco and 60c. in Dallas, during month; Boston reports decline of \$1 per M., delivered. New York quotations are \$19 per M., wholesale, at dock, against \$19@20, one month ago and \$15@15.50, one year ago. Hollow tile declined slightly in Philadelphia and Atlanta during month.

Lumber—Output increased 5,016,482 ft.; shipments, 3,298,724 ft. and new business, 6,221,976 ft., for the entire country, during week ended Nov. 24. General price decline in pine, fir, hemlock and spruce. Minneapolis, however, reports rise of \$1 per M. ft. in 8-in. Douglas fir timbers.

Explosives—Advance of 1c. in Boston and decline of 3c. per lb. in Atlanta, on 60 per cent gelatin dynamite.

Scrap—No. 1 machinery cast and heavy melting steel up \$1 per ton in New York.

Linseed Oil—Raw oil 95c. f.o.b. New York, against 98c. per gal. (5 bbl. lots) one month ago. Declines reported in Chicago and San Francisco; slight rise in Minneapolis.

Price advances since last month are indicated by heavy type; declines by *italics***PIG IRON**—Per Gross Ton—Quotations compiled by The Matthew Addy Co.:**CINCINNATI**

San Francisco and New York quote on hollow partition tile.

STRUCTURAL MATERIAL—Following are base prices f. o. b. mill, Pittsburgh and Birmingham, together with quotations per 100 lb. from warehouses at places named:

		Birmingham		Warehouse		San Francisco	
		Pittsburgh	Mill	New York	St. Louis	Chicago	Dallas
Beams, 3 to 15 in.	\$2.50	\$3.00	\$3.64	\$4.20	\$3.45	\$3.30	\$3.60
Channels, 3 to 15 in.	2.50	3.00	3.64	4.20	3.45	3.30	3.60
Angles, 3 to 16 in., 1 in. thick.	2.50	3.00	3.64	4.20	3.45	3.30	3.60
Tees, 3 in. and larger.	2.50	3.00	3.64	4.20	3.45	3.30	3.60
Plates, 1 in. thick and heavier.	2.50	3.00	3.64	4.20	3.45	3.30	3.60

RIVETS—The following quotations are per 100 lb.:

		Warehouse		San Francisco		Dallas	
		Pittsburgh	Mill	New York	St. Louis	Chicago	Dallas
1 in. and larger	\$2.65	\$2.85	\$3.00	\$3.85	\$3.75	\$4.15	\$4.90

		CONCRETE HEAD RIVET		San Francisco		Dallas	
		Pittsburgh	Mill	New York	St. Louis	Chicago	Dallas
1 in. and larger	\$2.85	\$3.00	\$4.50	\$3.95	\$3.85	\$4.35	\$5.20
1 in. and 1/2 in.	\$3.00	\$3.15	4.66	4.11	4.00	4.70	5.55
1 in. and 3/4 in.	\$3.25	\$3.40	4.90	4.35	4.25	4.90	5.60

Lengths shorter than 1 in. take an extra of 50c. Lengths between 1 in. and 2 in. take an extra of 25c.

NAILS—The following quotations are per keg from warehouse:

		Warehouse		San Francisco		Dallas	
		Pittsburgh	Mill	New York	St. Louis	Chicago	Dallas
Wire	\$3.00	\$3.80	\$4.25	\$4.55	\$3.34	\$4.95	\$5.00
Cut		4.45	\$3.85	\$3.75	5.75	3.64	5.00

SHIP SPIKES—Current prices per 100 lb.:

		San Francisco		Seattle	
		Pittsburgh	Mill	New York	St. Louis
In.		\$9.85	\$7.65	\$8.00	\$7.75
1 1/2		7.80	6.30	6.10	7.70
2		7.75	6.15	6.10	7.70

Pittsburgh base in lots of 200 kegs or more, \$3.50.

PREPARED ROOFINGS—Slatesurfaced roofing (red and green) in rolls of 108 sq. ft. costs \$2.31 per lb. in less than carload lots f.o.b. Philadelphia.

Single shingles, red and green slate finish, cost \$5.75 per square (sufficient to cover 100 sq. ft.) in less than carload lots, f.o.b. Philadelphia. Strip shingles (4 1/2 in. f.o.b. Philadelphia, 1 lb. \$5.80 per square.

ROOFING MATERIALS—Prices f.o.b. New York, in less than carload lots:

Tar felt (14 lb. per square of 100 sq. ft.) per ton.	\$67.50
Tar pitch (in 400-lb. bbl.) per 100 lb.	1.62
Asphalt roofing (in barrel), per ton, f.o.b. plant.	38.75
Asphalt felt (heavy), per ton, f.o.b. plant.	75.00
Asphalt felt (heavy), per ton, f.o.b. plant.	75.00

* Delivered in Metropolitan Dist., \$3.00 additional.

WINDOW GLASS—Double strength, box list, united inches, 34, "AA" grade, at discount of 85 per cent from standard lists, f.o.b. New York; "A" grade less 84 per cent and "B" grade, 87 per cent.

SHEETS—Quotations are per 100 lb. in various cities from warehouse also the base quotations from mill.

	Pittsburgh	St. Louis	Chicago	San Francisco	New York
Blue Annealed	Large Mill Lots				
10.....	\$3 00	\$4 45	\$4 00	\$7.00	\$4 50

MISCELLANEOUS

STEEL SHEETPIILING—The following price is base per 100 lb. f.o.b. Pittsburgh, with a comparison of a month and a year ago:

	Dec. 6	One Month Ago	One Year Ago
	\$2.65	\$2.65	\$2.50

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	Eastern Territory
Hercules red strand, all constructions	20%
Potent flattened strand, special steel wire rope	20%
Potent flattened strand, iron rope	5%
Plow steel round strand rope	35%
Special steel round strand rope	30%
Cast steel round strand rope	20%
Round strand iron and iron tiller	5%
Galvanized steel rigging and guy rope	75%
Galvanized iron rigging and guy rope	+12%

California, Oregon, Nevada and Washington Discount: 5 points less than discount for Eastern territory.

Wyoming, New Mexico and Colorado: Discount 5 points less than discount for Eastern territory.

Arizona: Discount 10 points less than discount for Eastern territory.

Montana, Idaho and Utah: Discount 10 points less than discount for Eastern territory.

North Dakota, Nebraska, Kansas, Oklahoma and Texas: Discount 5 points less than discount for Eastern territory.

MANILA ROPE—For rope smaller than 1-in. the price is 1/2 to 2c. extra; while for quantities amounting to less than 600 ft., there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: 1-in., 8 ft., 1-in., 6; 1-in., 4; 1-in., 3; 1-in., 2 ft. 10 in.; 1-in., 2 ft. 4 in. Following in price per pound for 1-in. and larger, in 1200-ft. coils:

Boston	\$0.151 @ 0.17	New Orleans	\$0.171
New York	.17	Los Angeles	.20
Chicago	.18	Seattle	.18
Minneapolis	.171	St. Louis	.191
San Francisco	.16	Montreal	.22
Atlanta	.25	Detroit	.20
Denver	161 @ 16	Baltimore	.18
Cincinnati	.19	Kansas City	.201
Dallas	.21	Birmingham	.201
Philadelphia	.17		

EXPLOSIVES—Price per pound of dynamite in small lots:

	40%	60%
New York	\$0.27	\$0.295
Boston	.25	.27
Kansas City	.2225	.2475
Seattle	.165	.19
Chicago	.22	.25
Minneapolis	.1917	.2123
St. Louis	.2225	.2475
Denver	.2025	.2275
Dallas	.225	.302
Los Angeles	.1975	.2225
Atlanta	.23	.2550
Baltimore	.22	.23
Cincinnati	.225	.25
Montreal	.195	.235
Birmingham, del. prod.	.16	.17
New Orleans	.195	.22
San Francisco	.1625	.1925
Philadelphia	.215	.24

CHEMICALS—Water and sewage treatment chemicals, spot shipments in carload lots, f.o.b. New York:

Sulphate of aluminum, in bags, per 100 lb.	\$1.40 @ 1.50
Sulphate of copper, in bibl, per 100 lb.	5.00
Sulphate of iron, in bags, per 100 lb.	1.00 @ 1.15
Chlorine, liquid, cylinders, 100 lb., per lb.	.081 @ .09
Hypochlorite of lime (bleaching powder) in drums, per 100 lb.	1.75

FREIGHT RATES—On finished steel products in the Pittsburgh district, including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire rails, rivets, spikes, bolts, flat sheets (except finished), chains, etc., the following freight rates are effective in cents per 100 lb., in carloads of 36,000 lb.:

Baltimore	\$0.31	Detroit	\$0.20
Birmingham	.58	Kansas City	.735
Boston	.365	New Orleans	.67
Buffalo	.265	New York	.34
Chicago	.34	Pacific Coast (all rail)	1.341
Cincinnati	.29	Philadelphia	.32
Cleveland	.215	St. Louis	.43
Denver	1.27*	St. Paul	.60

* Minimum carload, 40,000 lb.
† Minimum carload, 50,000 lb., structural steel only; 80,000 lb. for other iron or steel products.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, DECEMBER 13, 1923

Number 24

Write Your Congressman

NO FISCAL proposal of recent years has caught the attention of the country as has Secretary Mellon's tax reduction plan now before Congress. Backed by the President's strong indorsement this recommendation for a kind of taxing that will relieve the middle class directly, and the great body of the untaxed indirectly but no less surely, has become the leading issue before Congress. The soldiers bonus and the desire to penalize the very rich stand in the way of favorable action but Congressmen, after all, want to do what they think their constituents want. Now is the time for every citizen, whether or not he has ever done such a thing before, to write his Congressman and urge upon him the justice and desirability of the Mellon plan. A vociferous minority can only be overcome by an equally vociferous majority.

Remaking the Railroads

THE preliminary reports of the various committees on transportation of the Chamber of Commerce of the United States are most promising of an informing conference next January. When groups of business men in all lines of activity get together on a problem of such common interest an awakening of thought is bound to result and at the present juncture solid thinking by a number of people is the most necessary preliminary to any discussion of the railroad question. The business men of the country can not remake the Transportation Act but they can activate Congress to a sane consideration of any such remaking as will be proposed.

Transit Benefit Assessments

WHILE everyone knows that raising money for public works is frequently more difficult than building them, the emphasis given to this fact in the report of Detroit's rapid-transit commission is decidedly noteworthy. Details such as planning the system of routes or designing structures are boldly put to one side in the report, and the commission asserts that until the basic question of a financial plan is decided there can be only harm in proposing routes or designs. A very large sum of money will be needed to provide Detroit with rapid transit, while the city's available bond-issue capacity is so small that it would hardly build a mile of line. This constitutes the problem. The commission proposes to solve it by assessing the benefits on the property adjacent to the lines. Benefit assessment would have the double advantage of preventing the piling up of a burden of overhead on the taxpayer, and collecting for the public benefit a share of the unearned increment created by the public improvement. As a solution of the bond-limit difficulty the method has immediate interest to many cities besides Detroit. Probably every city that is thinking of rapid transit has the same problem of needing more money than its financial resources can supply; and to a certain degree this

remark might be extended beyond the field of rapid transit. If judicious application can be made of the principle of placing the cost of such works on local benefits, the way will be clear to do much badly-needed municipal work at present held in abeyance by lack of funds. The justice of the method—again, where judiciously applied—is its special recommendation. In a very similar and fully as interesting a case, that of the Moffat tunnel, which is also described in this issue, the test of Supreme Court interpretation has been obtained in favor of the method.

Coal Stock Piles Control the Price

THE striking relation between the reserve in consumers' stock piles and the spot price of coal is emphasized by the Geological Survey's report on the economic phases of coal storage. The report presents two charts, one a curve of the spot price of coal and the other a mass diagram of consumers' stocks. Separately the charts do not show much, but when superimposed it becomes evident immediately that every time stocks have fallen below 30,000,000 tons the price has immediately increased and when they have fallen below 20,000,000 tons the market has been thrown into a state of panic. Production in itself is not the controlling factor, for times of high production have frequently been marked by high prices due to consumers' nervousness over their lack of reserve. The lesson is evident. Consumers collectively can control the market. The individual can profit to the full from a policy of storage by storing more coal than his neighbor. Then, when his neighbor is in distress and is bidding up the price to scarcity levels, he can stay out of the market. If he stores less than his neighbor, he will have to enter the market first and will be there when the price is at its peak. Consumers, either individuals or concerns, should not begin to use their reserves while the price is normal. Instead, they should continue to buy for their current needs until prices become abnormal, when they can fall back on their reserves. Such a policy will give them the full benefit of their reserves, and will, at the same time, insure their not having to enter the market until after the peak has passed.

Minnesota Joins the List

MINNESOTA has gone as far as the law allows in disapproving, through its State Board of Health, plans for the direct-oxidation or lime-electrolytic process of sewage treatment submitted by the city of Austin. In this it comes as nearly as it feels it legally can to following the action of the New Jersey Board of Health which has refused permits for the same process to Phillipsburg and Trenton. Ohio is still delaying action on the Lima plans for the direct-oxidation process. The engineering division of the Provincial Board of Health of Ontario has for months past been running

parallel tests of limed sewage passed (1) through an electrolizer and (2) directly to a sedimentation basin. In Pennsylvania it appears that the Allentown plant has been given a conditional approval but that the state health authorities are waiting for enough sewage to reach the plant to permit a full-capacity test of one of three 1-m.g.d. units completed some two years ago. In view of conditions elsewhere the action of the Minnesota Board of Health is not surprising. The opinion of the Minnesota attorney general, noted elsewhere in this issue, suggests to us the question, should not the authority vested in a state board to approve or reject plans for sewage-works be accompanied by power to exclude from the plans any expensive element of undemonstrated value, even though that element may not be detrimental to the end result of the whole process? Whatever the answer may be when viewing the question in its relation to the police power of the state, sound economics demand protection to the municipal treasury. Assuming that any state board of health lacks the power to prevent the expenditure of money on unproved processes then the least that it should do is to point out clearly what the risk is—as the Minnesota board has done.

A Time for Tribute

TWENTY years ago next Monday man made his first successful flight in a heavier than air machine. It will be worth while for every one that day to pause and give thought to those two persistent Dayton shopmen who first flew their little fluttering plane over the Carolina sand dunes on Dec. 17, 1903. The airplane has by no means revolutionized the world but it has removed just so much further man's limitations and whatever does that, whether it be the alphabet, or the steam engine or radio, makes life just that much more worth living. The Wright brothers did not develop the airplane out of nothingness but they had the true inventor's instinct of persistent experiment with those things their predecessors had already made known and the faith in their own ability to do what no man had done before. Those of us whose horizon—both spiritual and actual—has been enlarged by their genius can do no less than pay them the tribute of a moment's remembrance.

No Progress

ALITTLE less than two years ago it appeared certain beyond doubt that a step forward would be made in the long struggle against bad building. The evil results of bad building had just become manifest in shocking manner. The roof of the Knickerbocker moving-picture theater in Washington had fallen down during a performance, crushing nearly a hundred of the spectators to death; only a few weeks earlier half a dozen men had been killed in the collapse of an uncompleted moving-picture house in New York, to be known as the American. There was evidence of flagrant violation of sound practice in the planning and erection of the buildings. Universal alarm and indignation arose over the tragic failures. But these feelings were tempered by the belief and hope that the inevitable judicial prosecution and due punishment of those involved would have the effect of discouraging the continuance of bad building practices. Events of the past few days, however, seem to have finally disappointed this hope. Prosecution of the owner and contractor in the American case failed,

the trial judge vacating the indictments for technical defects. Almost simultaneously the trial of several damage suits against the owners of the Knickerbocker theater by relatives of victims reached an equally disappointing end, with verdicts in favor of the owners. Long before this the criminal prosecution of the parties to the Knickerbocker job was ended, when a judge voided the indictments and the district attorney then refrained from attempting to bring new indictments. In the face of such a record it is not possible to feel satisfied with the operations of legal process. But—to think of the future—it is necessary to realize the hard fact that the sacrifice of a hundred dead has not brought us nearer to sound building, and that the fight of past years must continue if we are to stay the arm of the incompetent, the neglectful, and the fraud.

Increased Motor Vehicle Imposts

WHAT should the car owner pay as his share of the cost of highway improvement? Answers range between a moderate charge sufficient to maintain improved roads and the total cost of road construction and upkeep. The dispute wages endlessly.

Meanwhile the people everywhere, through acts of legislature, are adding to the taxes on the car user. This year one state, Utah, has radically reduced motor vehicle license fees and one, New Hampshire, has revised its license fees slightly downward, but in every other state where there has been any change it has been an increase. This year also 32 states have placed a tax on gasoline or raised the existing tax until now 37 states impose taxes ranging from one cent to four cents a gallon. Gas taxes barely failed of enactment, generally by veto, in half a dozen other states.

Two facts are obvious in all automobile legislation, that which failed and will again come up for consideration and that which was enacted: (1) The public has determined that the car user shall pay largely for road improvements and (2) the public is convinced that heretofore the payment has not been as large as it in justice should be. This brings us again to the original question: What is a fair payment?

Recently A. R. Hirst, state highway engineer of Wisconsin, has undertaken to answer this question with mathematical precision. He has evolved a formula, published in another column, for computing the charge against car owners for highway service. According to this formula the charge at present is about half of the amount it should be. This charge, Mr. Hirst proposes, should be made in the form of license fees and a tax on gasoline consumption which is held to be the best measure of road use by motor vehicles. It is not, however, in the character of the imposts proposed by Mr. Hirst that concern will lie but in their magnitude. He suggests a minimum of five cents and a maximum of ten. He will have his critics and they will not be kind.

Fundamentally, however, the question is not rates but whether the automobile should pay a greater share (about twice as much) than it is now paying of the cost of road service. As Mr. Hirst points out we cannot let thought of what has been hamper our conclusions. Roads are improved today for motor vehicles. Not a thought in design or construction of the modern main road is for other than motor vehicle service. It is the user who must pay. And with 14,000,000 motor vehicles being used the payment has to be large.

Another Industrial Message

FEW messages to Congress have had more intrinsic importance than the one President Coolidge has just delivered. As a program which this Congress will follow it has only the force of the executive desire, which this year is not commanding because of the closeness of the party representation in Congress and the uncertainty of the action of the so-called insurgent group from the Middle West. But as an indication of the political faith of one of the leading candidates in the coming Presidential election the document becomes practically a party platform, besides being a revelation of the mind of one who for excellent reasons has not thought it fitting since he became a national figure to express an opinion on our national problems.

The message is obviously revelatory of the Coolidge psychology. To a people accustomed to the rather turgid rhetoric of presidential messages, this one at first reading seems deadly dull. There seems to be no emphasis, no high spots or clear call to action. It requires a second reading to get the tone of the message, to realize that it is a model of compression with few waste passages and that the mere mention of a subject is in itself an emphasis of that subject. One sentence—paragraphed by itself, and all there is on a most disputed issue—"But I do not favor the granting of a bonus," is more expressive than pages of argument. Unless the character analysts of the press are all wrong this means that those congressmen who think they were elected on a pledge for a bonus will have occasion to vote twice on that question—before and after the Presidential veto.

Reading the message, then, as the framework of an administration policy and a platform for a candidacy, we note the same insistence on industrial problems which has marked the presidential messages of recent years. The old issues, particularly the currency and the tariff, are hardly noted. In their stead are taxes, the railroads, the farmers, national improvements and coal—and all of these are either directly industrial or have repercussions of the greatest moment in industry. In two of these sections, on taxes and the railroads, the message is strong and commendable. On the others it tends too much toward generalization where a definite stand might have been expected.

The President comes out flat-footed for the Mellon plan of tax-reduction and in so doing hammers home the too frequently forgotten axiom that lowered taxes benefit those who do not pay a direct tax quite as much as those who do. In characteristic short sentences he says: "For seven years the people have borne with uncomplaining courage the tremendous burden of national and local taxation. These must both be reduced. The taxes of the nation must be reduced now as much as prudence will permit, and expenditures must be reduced accordingly. High taxes reach everywhere and burden everybody. They bear most heavily upon the poor. They diminish industry and commerce. They make agriculture unprofitable. They increase the rates on transportation. They are a charge on every necessary of life. Of all services which the Congress can render to the country, I have no hesitation in declaring this one to be paramount. To neglect it, to postpone it, to obstruct it by unsound proposals, is to become unworthy of public confidence and untrue to public trust. The country wants this measure to have the right of way over all others." This is sound doctrine, but it is

one that needs the strong hand of the executive to back it up.

Concurrent with the demand for lower taxes runs a reiteration of the Harding policy for an adherence to a federal budget and a plea for a constitutional amendment against tax-exempt bonds. The President will probably be able to carry the budget through against the congressional forces who fight any reduction of their prerogatives but the possibility of the states depriving themselves of tax-exemption seems quite remote.

Much is said in the few paragraphs on the railroads and most of it is good. There is a rather timorous defense of the Labor Board, to be sure, but the plea for a continuation of the Transportation Act is excellent. The onus of the complaints against that act lie in the interpretations of the term "value" by the courts and the Interstate Commerce Commission and not in the "fair return" clause of the act itself. The President well says that "unless the government adheres to a rule of making a rate that will yield a fair return, it must abandon rate-making altogether." A government activation of consolidation, as suggested in the message, offers the best promise of general rate relief, though the recommended general reorganization of the rate structures is imperative as a means to early adjustment of unfair conditions.

The message adds nothing to the solution of the coal or of the immigration problem. Both passages are fair enough statements of the issues but on neither does the President indicate a way out. The same might be said of his comments on the great national improvements, though the adherents of the St. Lawrence waterway and power scheme may find some encouragement in his comments on that project. The real Muscle Shoals issue—that is the legality and fairness of the Ford 100-year amortization offer—he avoids entirely though he does intimate that there should be a much more reliable promise of fertilizer manufacture at Muscle Shoals than Mr. Ford has ever made. On all these questions the expressions do not have that clear promise of future policy that would have been welcome.

On several other questions of interest to engineers the message is short but, remembering the general tone of the document, quite satisfactory. The administration favors highway development and reforestation and a proper departmental reorganization, minus the impossible Army-Navy combine. In reclamation, the necessity for some readjustment of charges is recognized but no encouragement is offered for complete repudiation. The only other two major sections of the message, those on foreign relations and on agriculture, have at least a collateral industrial importance for nothing would contribute a greater measure to industrial stability than a settlement of the difficulties in Europe and an alleviation of the depression in agriculture. In discussing both of these subjects the President takes refuge again in the concise statement of fundamentals which may mean much when interpreted by future action but which lacks something as a guide to what that future action must be.

It is clear that the big national problems, as selected by the President of the United States, are mainly industrial. Let the engineers of the country in reading the message note that fact, and in so noting recall the responsibility they have of educating their less interested fellow citizens as to the fundamentals of industrial needs.

Six-Mile Moffat Tunnel Through the Rocky Mountains

Novel Plan to Finance Railway Tunnel Replacing Open Summit Pass—Small Parallel Pilot Tunnel Assists Construction—Excavation Progress to Dec. 1

AN IMPORTANT step both in tunnel work and in the development of railway transportation facilities was taken in the recent award of a contract for constructing the six-mile Moffat Tunnel through the Continental Divide, about fifty miles west of Denver, Colo. In several ways this enterprise is of exceptional interest: (1) The tunnel will be of unusual length; (2) intermediate headings are to be driven from connections with a parallel heading or pilot tunnel; (3) the tunnel is to be built as a public work for improving the railway system of the state; (4) funds are to be provided by an improvement district established by law for this purpose and authorized to issue bonds; (5) the pilot tunnel may be utilized for a water conduit giving the city of Denver a new supply from sources on the west slopes of the range. A plan and profile of the line are shown in Fig. 1.

History of Tunnel Project—A tunnel under James Peak was proposed originally by the late D. M. Moffat, promoter and president of the Denver & Salt

Financial conditions have prevented the building of the tunnel and the completion of the railway to its western connections at Salt Lake City. The present line extends 255 mi. from Denver, El. 5,170, to Craig, Colo., El. 6,175. Its heavy grades, high altitude and snow troubles at the crossing of the Divide are seriously detrimental to operating efficiency and economy. When completed, the Denver & Salt Lake R.R. will give a route of about 565 mi. between Denver and Salt Lake City, as compared with 620 mi. by the Union Pacific R.R. and 745 mi. by the Denver & Rio Grande Western R.R. It has been suggested that in advance of the completion of this new railroad a 40-mile connection from McCoy, on the Denver & Salt Lake R.R., west of the tunnel, to Dotsero on the Denver & Rio Grande Western R.R., would give a combination route of about 600 miles.

In view of the potential importance of a new railroad with a low-grade line across Colorado, both for local development and as a favorable transcontinental route, various attempts have been made to provide public assistance for the tunnel project. In 1913, the city of Denver adopted an amendment to its charter authorizing the issue of bonds and the creation of a commission to build and operate a tunnel. This commission entered into negotiations with the railroad and recommended a bond issue of \$3,000,000. The railroad was to pay the remainder of the cost, which was estimated at \$4,200,000. The tunnel was to be large enough for a water conduit and was to be available for use by any other railroad on payment of trackage rights and a share of the annual interest on investment. This project was noted in *Engineering News*, Jan. 29 and July 16, 1914, pp. 222 and 156. In February, 1914, the bond issue was carried by a large vote; but in July, 1914, the Colorado Supreme Court decided that the city had no right to issue bonds for this purpose.

The next attempt was to have the tunnel built as a state enterprise to be used by all Colorado railways having transcontinental traffic, since it would provide a route much more favorable than that of any other line across the state. In 1918, the Colorado legislature passed a law providing for a railway commission to study the situation and for a referendum vote on a constitutional amendment to authorize a bond issue for a tunnel. This commission recommended an issue of bonds for \$18,550,000 for the Moffat tunnel and for two smaller tunnels on other routes considered to warrant improvement in the interests of the state. It has been suggested that this extension of the original project, with the large sum involved, led to disapproval by public opinion. At any rate, the proposed bond issue was defeated by referendum vote in November, 1920. Particulars of this state-aid project were given in *Engineering News-Record*, April 8, July 1 and Dec. 30, 1920, pp. 716, 44 and 1302.

Plans for municipal and state aid having failed, a new and highly unusual method was then suggested in the way of providing funds by assessments in an "improvement district" benefited by the tunnel. This plan, similar to that of drainage and irrigation districts,

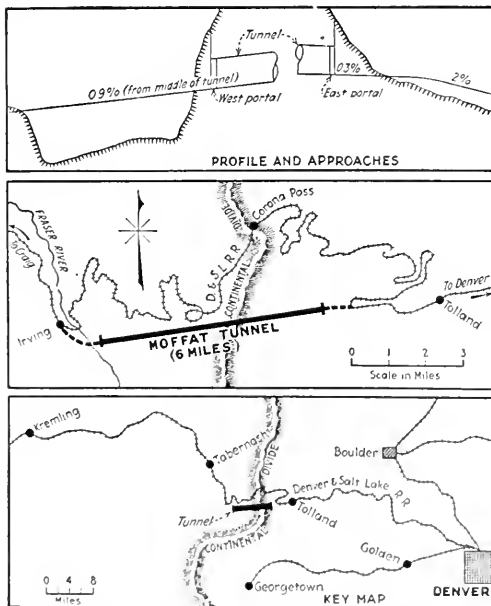

FIG. 1—MAPS AND PROFILE OF MOFFAT TUNNEL LINE

Lake R.R. This line was intended to be a specially favorable link, with maximum grades of 2 per cent, in a transcontinental route through Colorado, but also to develop a rich agricultural and mineral district far from existing railroads. Pending the construction of the summit tunnel at about El. 9,200, an open line was built having long grades of 4 per cent and numerous curves of 16 deg., with curvatures forming a heavy proportion of the total length. This line crosses the summit in Corona Pass, at El. 11,660.

proved successful. Early in 1922 the Colorado legislature passed the Moffat Tunnel Improvement District law, providing for the organization of a district with authority to issue bonds. The law also provided for a tunnel commission and limited the cost of the work to \$6,720,000.

This third method, outlined in *Engineering News-Record*, May 18, 1922, pp. 811 and 836, received public approval. Further delay was caused, however, by a dispute as to the constitutionality of the bonds. In a friendly suit to settle this point, the favorable decision of the courts closed the preliminary and promotional stages of the tunnel scheme. Plans were then completed and proposals were invited twice on account of irregular bids in the first case. Finally, in September, 1923, the contract was awarded on terms as noted in *Engineering News-Record*, Sept. 27 and Oct. 11, 1923, pp. 532 and 615.

Description of Tunnel—According to the present

a clear height of 24 ft. above subgrade and a clear width of 16 ft. in solid rock and 16½ ft. in timbered portions, as shown by Fig. 2. Complete timber lining includes 2-in. side lagging and 4-in. roof lagging, but in places only roof timbering may be needed, supported by posts or by wall plates. All spaces behind lagging are to be filled with loose rock, which will be grouted if required.

Concrete lining, which is expected to be used only near the portals, will be placed behind the neat line, the lagging being removed for this purpose. This concrete, proportioned 1:7, will be made by mechanical mixers. Pneumatic placing is permitted. If the rock breaks so high as to permit access above the arch after concreting, the arch will be given a definite thickness and the space above it filled with dry stone packing. Otherwise the entire space between the arch form and roof will be filled with concrete. Permanent timber lining will be of Oregon fir or lodgepole pine. This pine

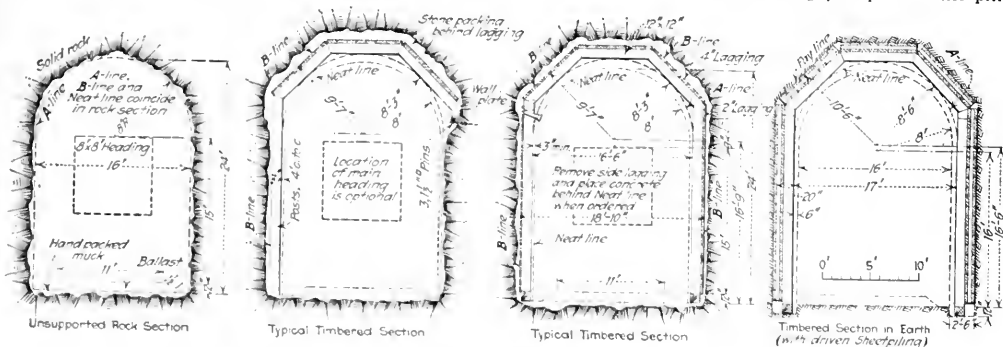

FIG. 2—RAILWAY TUNNEL THROUGH CONTINENTAL DIVIDE IN COLORADO

plans the Moffat Tunnel will be 32,150 ft. in length, or almost exactly six miles. The east portal is three miles beyond Tolland, on the Denver & Salt Lake R.R., and the west portal one mile from Irving, these two stations being about 50 and 80 mi. respectively from Denver. The tunnel will be on tangent throughout. A grade of 0.3 per cent will ascend from the east portal at El. 9,198 to the summit at mid-length and at El. 9,242; thence on a grade of 0.9 per cent will descend to the west portal at El. 9,085. Maximum grades of 2 per cent are provided on the approaches, which are short and consist largely of fills.

The approximate quantities on which the bids and contract are based are given in the accompanying table:

QUANTITIES FOR MOFFAT TUNNEL

Railroad tunnel:	
Earth	200 cu.yd.
Rock	365,000 cu.yd.
Water tunnel, cross-cuts and main headings; rock	157,500 cu.yd.
Open cut:	
Earth	30,000 cu.yd.
Rock	15,000 cu.yd.
Concrete masonry in tunnel	15,000 cu.yd.
Permanent timber lining	1,900 M. ft. b.m.
Timber lining in water tunnel	160 M. ft. b.m.
Dry packing in tunnel	4,800 cu.yd.
Cordwood packing in water tunnel	250 cords
Steel pipe for grouting	200 lin.ft.
Cement	8,000 bbl.
Ballast in tunnel	15,300 cu.yd.

Excavation and Lining—That probably the entire work will be in gneiss rock was stated in a report of the State Geologist of Colorado in 1914. In section the tunnel as now proposed, for a single-track line, will have vertical sides, an arched roof and a flat floor, with

or other satisfactory timber; will be used for the headings and for the pilot tunnel.

In the typical sections, Fig. 2, the A line is that beyond which no unexcavated material, timbering or support may extend, so that it is the line of minimum thickness of masonry lining or the neat line of excavation where no such lining is used. The B line is the limit of excavation to be paid for, and in some cases it is also the payment line for masonry.

Headings 8x8 ft. are planned, as shown, but the location of the heading in relation to the tunnel section is optional with the contractor. The estimated quantities of excavation are 10.83 and 14.95 cu.yd. per lineal foot for lines A and B respectively in the main tunnel, and 2.37 cu.yd. for the 8x8-ft. headings. It is provided that a planimeter may be used for measuring areas in estimating quantities where the computation of areas by geometric methods would be laborious.

Pilot Tunnel—A special feature of the work is the pilot tunnel or water tunnel, 8x8 ft., driven approximately 75 ft. south of and parallel to the main tunnel, as shown in Figs. 3 and 4. Cross-cuts of the same section will be driven at intervals of about 1,500 ft. and from these the main headings can be driven in both directions. This pilot tunnel will have the same profile and grades as the railway tunnel but will be at an elevation about 7 ft. above that of the latter. The excavation quantity is estimated at 2.4 and 3.3 cu.yd. per lineal foot on lines A and B respectively. Cordwood packing around the timber sets will be used in the pilot

FIG. 3—PILOT TUNNEL INCREASES NUMBER OF MAIN HEADINGS

tunnel and also in the cross-cuts and main headings (see Fig. 4).

The pilot tunnel will serve for ventilation of the main headings and for the handling of materials and muck trains. After the completion of the work it is intended to use this smaller tunnel as a conduit for the supply of water to Denver, but the proposed connection with the Fraser River is not included in the present contract.

Rapid Tunneling—Rapid progress in tunneling is desired and the information given to bidders by the Tunnel Commission contained the paragraph noted below. The specifications also provide that in the purchase of equipment and supplies Colorado products are to be given the preference when quality and prices are equal.

"It is the purpose of the board to build the works in the shortest time consistent with good construction. To this end contractors will be required to use improved methods and appliances for doing the various parts of the work. Complete and well-designed construction plants and effective organization will be insisted upon. Attention is called to the magnitude of the work and to the need for machinery and other equipment of unusually large capacity."

Under the contract, the contractor is to begin work within ten days after a notice to this effect, and within thirty days from such notice he is to have assembled and installed sufficient plant for effective excavation at each portal. The entire work is to be completed within forty-six months from the first notice to begin operations.

Power and Light—The Moffat Tunnel Commission has contracted with the Colorado Power Co. for 1,000

hp. of 44,000-volt current, delivered at the east portal. A 30-mi. transmission line will be built, as noted in *Engineering News-Record*, July 12, 1923, p. 77. This contract will be assumed by the tunnel contractor, except as it relates to operation of the completed tunnel. The contractor will provide a telephone system connecting both ends of the tunnel and serving the local offices and the headings. Electric light is to be used, and in portions of the work where men and materials must pass the illumination must be equivalent to one 40-watt lamp for each 50 ft. of tunnel. Adequate special illumination must be provided where tunneling, timbering, concreting and other work is being done. All power machines or tools within the tunnel are to be operated by electricity or compressed air.

Ventilation—Ventilating plants, preferably on the plenum system, are to be of sufficient capacity to deliver at least 24,000 cu. ft. of free air per minute to the several headings. If high-pressure air is used to clear the headings after blasting, it should give at least 1,500 cu. ft. per minute in each heading.

Cleaning and Ballasting—Broken stone ballast of 3-in. to 2 1/2-in. size is to be laid by the contractor to the level of the bottom of the ties. Before this ballast is placed the floor and sides of the tunnel are to be cleared of dirt, loose stone and other material and then washed with a stream of water having a pressure of at least 30 lb.

Sanitary Requirements—Two camps are to be established by the contractor, and the specifications lay stress on enforcement of the sanitary regulations. Since the work is at an elevation of about 9,200 ft., where intense cold and heavy snow prevail during part of the year, pulmonary and other diseases are likely to become epidemic unless great care is taken. Sleeping quarters are to provide for each inmate 400 cu. ft. of air, 2 1/2 sq. ft. of window area and 0.3 sq. ft. of ventilating opening which cannot be closed. The floor level is to be at least a foot above the ground. Houses are to be screened against mosquitoes and flies, and no stable or yard for animals is to be within 150 ft. of a dwelling house. The contractor is to supply blankets and pillows and to keep them clean. Each man is to have a bed or cot, and in single men's quarters not more than two men may occupy one room.

Near each portal and connected to the tunnel by a covered passage is to be a dry room where the tunnel men can change their clothes before and after work. This room is to be kept warm and fitted with shower baths and individual wash-basins. Lunches must be sent to men working so far in the tunnel that they cannot come to the mess room for meals. Hospital facilities are to be provided at each camp, in charge of medical and surgical practitioners, preferably those who have had experience in field and camp sanitation work under army or civilian conditions.

Water supply, drains, sewers and sewage disposal plants are to be provided. Garbage is to be removed promptly and placed in air-tight receptacles. All gar-

FIG. 4—SECTIONS OF PILOT TUNNEL, CROSS CUTS AND MAIN HEADINGS

bage, refuse, manure, surgical bandages and general dust and rubbish must be disposed of every day by incineration or other approved methods. To facilitate the commencement of work the Tunnel Commission began the construction of sewer and water systems and housing facilities before the award of the contract for the tunnel.

Progress on the Moffat Tunnel—Up to Dec. 1 work had advanced so that the east heading of the 8 x 8-ft. pioneer or water tunnel was 370 ft. underground, in solid granite, while the west heading was 630 ft. in gneiss and pegmatite, which requires timbering. The full installation of compressors, locomotives and other equipment had not been completed at that date.

Engineers and Contractors—All administration and construction work on behalf of the Moffat Tunnel Improvement District is under the Moffat Tunnel Commission, of which W. P. Robinson is president, with offices at Denver, Colo. This commission has appointed a board of consulting engineers composed of D. W. Brunton, L. D. Blauvelt, J. Vipond Davies and J. Waldo Smith. The chief engineer of the commission is R. H. Keays; the resident engineers are V. A. Kauffman, at the west end, and B. G. Coy at the east end; Clifford A. Betts is office engineer. On Sept. 18, 1923, the contract was awarded to Hitchcock & Taylor, of New York and San Francisco. A period of forty-six months is allowed for the completion of the work.

California Court Denies State Can Cancel Road Contract

Highway Commission Cannot Rescind Contract In Order to Divert Funds Elsewhere, Is Supreme Court Decision

BY PAUL F. FRATESSA

Attorney for California Highway Commission

SHORTLY after the present California Highway Commission took office it was deemed good policy to rescind a contract then in effect which had been awarded by the previous commission. The reason for this was that the cost of the work which was being done on the unit-price plan was found greatly to exceed the engineer's estimate and the new commission preferred to stop the work and apply the funds to more urgent work in other parts of the state. The contract in question was held by George Pollock & Co. and covered the construction of a highway along the ocean shore in Monterey County.

The new highway commission accordingly made an agreement with the contractor whereby the contract was to be cancelled and the state was to pay the contractor a stipulated amount, based on the estimated value of the work done on the contract up to that time, and taking into consideration that the contractor had been to the expense of moving in his equipment, constructing camps, etc. The contractor thereupon presented a claim to the State Controller for payment of the amount agreed upon. The controller refused to allow the claim and proceedings were instituted in mandamus to compel its allowance.

In a decision handed down by the Supreme Court of California, Sept. 20, Judge Meyers held that the State Highway Commission has no power to enter into an agreement with a contractor whereby a contract would be cancelled and the contractor paid for his time and

trouble. The decision in no wise affected the original contract, and the contractor is now proceeding to complete the work, this being the only apparent way in which he can collect for expenditures he has already made.

No Authority to Rescind Contract—The decision states: "By the execution of an authorized contract the state acquires certain legal rights and incurs certain liabilities which are fixed and ascertained, or ascertainable. Thereafter no one can either increase or diminish the rights of the state or increase or reduce its liabilities thereunder unless he has been vested with authority so to do by express grant or clear implication. The state having directed or authorized the making of the contract contemplates its performance and, as in the case of private individuals, the authority to breach such a contract is not to be implied from the mere grant of authority to execute the same.

"When, as here, the contract has been lawfully executed and has been performed in part, the amount which the contractor is entitled to receive for the work done is fixed by the terms of the contract. For the commission to pay him more than the contract calls for would, therefore, be to make to him a gift of public moneys, unless the commission has the power and authority to first breach the contract."

The court, continuing, recognized the fact that the law has vested in the highway commission a very great latitude of discretion and has given it "full possession and control" over all state highways and all expenditures for highway purposes, but held that the commission was limited in making contracts to follow the formalities specifically laid down by the law. That is, it can only enter into a contract for the doing of work and the expending of money, by advertising for bids or by following some other methods specially provided in the law.

The question as to whether the legislature might have passed an act authorizing the cancellation of this contract and reimbursing the contractor was not presented in this case.

Some Figures on Taxes

The National Industrial Conference Board has issued a comprehensive study of the growth of public expenditures, taxation and tax exemptions of the federal, state and local governments. Some of the significant facts brought out in this careful survey are: Total taxes paid in the United States in 1922 aggregated \$7,061,000,000. This amounted to 12.1 per cent or nearly one-eighth of the national income. It meant a cost of \$64.63 to every man, woman and child. Each person had to contribute the income of 6½ weeks to support the government in 1922, as compared with 3½ weeks before the war. State and local taxes formed 38 per cent of the total taxes. The public payroll included nearly 3,400,000 persons. Every eleven workers, 16 years of age and over, supported one public employee. The cost of salaries of public employees aggregated \$3,800,000,000, or \$91 for every person ten years of age and over gainfully employed, or \$35 for every man, woman and child. Direct and indirect taxes paid by farmers in 1922 were 16.6 per cent of their income. Those paid by the rest of the community were 11.9 per cent of their income. Real and personal property to the value of \$54,000,000,000, or about one-fifth of the national wealth, was exempt from taxation in 1921.

Determining Hydraulic Gradient in Chicago Water Tunnels

TO DETERMINE accurately the flow of water in the Southwest Lake and Land Tunnel in Chicago and thus learn the maximum that might be removed from it at Seventy-third and State Sts., to supply the new pumping station on Western Ave., a new method of measuring and recording water elevations was devised. By this method the n in Kutter's formula was found to be 0.019 in the 14-ft. section, 0.017 in the 12-ft. section and 0.016 in a 9-ft. section. M. B. Reynolds, acting assistant city engineer, then engineer in charge of pumping station operation, describes in the 1922 annual report to the city engineer the methods used as follows:

In the planning of the work of locating the hydraulic gradient it was at first proposed to use observers at the various shafts along the entire line, but after some study

WATER SURVEY APPARATUS USED TO MEASURE WATER LEVELS IN TUNNELS

and discussion this method was abandoned for the reason that the gages could not be read accurately, because it was usually impossible to place an observer in such a position as to be able to read the water level. Also, the fluctuations in the water level occurred at such short time intervals as to make accurate observations an impossibility.

The second method proposed was the placing of some type of recording gage, such as the standard type of tide gage, or the more recent diaphragm or bell devices that are in use for this purpose, at the various shafts. Experience with recording instruments of the above type proved that they were unreliable, especially where comparatively small differences of elevations must be determined accurately. Their use was therefore abandoned.

Since all available methods or instruments were considered unsuitable for the purpose of determining piezometric heights, an instrument was devised that eliminates all lost motion and will accurately record extremely small differences of elevation. It consists of a manometer M made of $\frac{1}{4}$ -in. iron pipe, a glass tube T of convenient length and a Pitometer Co.'s photo recorder, which consists of a lamp L and a drum D driven by a clock C . These recorders are in daily use in connection with water surveys of the division, and were therefore available. The manometers were made

approximately 12 ft. long from the bottom of the U to the point of connection with the glass tube.

In use the U bend of the manometer is filled with mercury to about half the height of the short leg; the remainder of both short and long legs is then filled with water. The glass tube is attached and filled with water to a convenient height, depending upon the location of the recorder; and a kerosene bubble B dyed with aniline dye, about 2 in. in length, is placed on the top of the water level in the glass tube.

Due to the irregularities of both glass tube and manometer the instrument is calibrated by placing a long glass tube on the short leg of the manometer and varying the head of water in this glass tube. In this manner an accurate calibration of the movement of the bubble is made.

The instrument is placed in the shaft at such a depth that the short leg of the manometer is always submerged, the glass tube placed in the recorder, a sheet of sensitized paper placed on the drum, and the lamp lighted. From the sketch it can be seen that all variations in the submergence H will be transmitted to the bubble B and an accurate and continuous record of every piezometric height will be recorded.

Four of these instruments were used in making the survey. Precise levels were run from standard benches to the shafts, and accurate elevations of the manometers were determined. Attempts were made to pass correct elevations from the shore to the crib by reciprocal leveling, but due to atmospheric conditions elevations were not considered sufficiently accurate for use. The established elevation of the crib gage was used in locating the manometer elevation of the crib. These four instruments were operated simultaneously, giving the piezometric heights for every instant throughout the 24 hours. During the run tests were made each day to check the accuracy of the indicating bubble by measurement of submergence at each instrument.

The value of Q or flow during each day's run was taken from the station instruments and is probably not more than 2 per cent in error.

The values of n were surprisingly high and some doubt as to their accuracy arose, but subsequent checks proved that the values originally determined were correct.

Half-Year Ocean Passenger Traffic 450,000

The Bureau of Research of the United States Shipping Board in its report on passenger traffic to and from the United States, classified under three heads: overseas, nearby (including Canadian and Caribbean) and non-contiguous United States territory, shows the following: New York leads all American ports in the overseas movement with a total of 208,359 passengers handled in the first six months of 1923. Second for the United States and first on the Pacific Coast comes San Francisco with 19,170, followed by Boston with 11,369 and Seattle with 6,046. The total movement of passengers for the six months in the overseas trade was 249,002, of which 152,436 entered and 96,566 departed. Third-class traffic made up more than one-half of the incoming passenger business, but less than one-third of outbound. Of passenger traffic with the nearby countries, chiefly first-class traffic, there was a total movement of 197,750 first-class passengers, while the entire overseas first-class movement of all coasts was but 56,396. Of the foreign districts the movement between the United States and the United Kingdom amounted to 64,210 passengers. Germany and the Scandinavian nations showed 78,737, while Holland, Belgium, France, and Spain were responsible for 41,770. The Oriental traffic, to China, Japan and the Philippines, totaled 22,679. South American ports handled but 7,939 passengers, of whom 6,265 sailed from or to ports on the east coast of South America and 1,674 from or to ports on the west coast of South America.

What Car Owners Should Pay for Road Building

Formula Proposed for Figuring Vehicle Imposts—Gas Tax Best Measure of Road Use—
Five-Cent Tax Generally and Ten-Cent Tax in Some States Proposed

By A. R. HIRST

State Highway Engineer of Wisconsin,
Madison, Wis.

A paper presented before the Annual Meeting of the Michigan Good Roads Association, Lansing, Mich., Nov. 6, 1923.

THE MOTOR vehicle owners of each state should each year pay for their highway service one-half of the total amount made available in that year to pay the cost of the state's highway program, after deducting from said amount the total amount made available to pay the cost of the state's highway program in the year 1904.

The year 1904 is selected as the basing year because quite dependable figures of highway expenditures in all states are available for that year, and because it quite accurately marks the real beginning of the motor era.

Please read the formula again before condemning it and note especially that its terms do not include the expenditures made in any year from the proceeds of bond issues, but only the portion of the cost of bonding paid in that year.

Applying this formula to a hypothetical case: In a certain state there was made available in 1904 to pay the cost of all highway work, \$10,000,000. There is to be made available \$40,000,000 in 1925. The amount the motor vehicle owners should pay in 1925 is one-half the difference, or \$15,000,000.

The formula means that there would be paid by property and from other sources of governmental incomes:

(a) The total cost of highways which they paid at the end of the era of horse-drawn transportation.

(b) One-half of the additional highway cost imposed upon government by the ownership and use of motor vehicles by individuals.

It of course means that the owners of motor vehicles would pay:

(a) One-half of the additional highway cost imposed upon government by his ownership of motor vehicles.

Translated into national figures the formula means that based on total highway expenditures of \$200,000,000 in 1914 and of \$1,000,000,000 in 1923, the motorist should have paid \$400,000,000 in 1923 for use on highways; this does not include the luxury tax and the personal property tax, neither of which is a tax for highways. Compared with the actual payment of \$200,000,000, this means that motorists should have paid \$200,000,000 more than they did pay in 1923, or approximately \$11 more per motor vehicle, on the average.

We expect that many will oppose any proposed application of the formula to specific tax problems. We do not claim that it is perfect. In meeting especial conditions in

certain states its arithmetical result would have to be modified by the application of common sense. We do claim, however, that it is of value as a guide to judgment. We do claim that it is the first mathematical formula proposed that recognizes the existence of the fundamental facts which should largely determine the relative part of the cost of highway programs to be paid by motor vehicle owners as such, and by other taxpayers as such.

Let us briefly summarize and comment upon the various common forms of taxation upon motor vehicles.

Motorization and Highways

In 1904 there were in operation in America about 58,000 automobiles. There were practically no motor trucks. In 1914 there were registered 1,711,339 automobiles and motor trucks. In 1919 there were registered 7,530,105 automobiles and motor trucks. In 1923, preliminary figures indicate a total registration of at least 14,000,000 automobiles and motor trucks.

In 1904 the rural highway expenditures of America are reliably computed to have been \$59,527,000; in 1914, \$240,264,000; in 1919, \$389,466,000; and in 1923 they are estimated to be at least \$800,000,000. Roughly, the rural highway expenditures per motor vehicle in operation in 1904 were about \$1,026; in 1914, \$140; in 1919, \$52; and in 1923, \$37. The expenditures per motor vehicle in 1923 were 5 per cent of those of 1904; 40 per cent of those of 1914; and 110 per cent of those of 1919.

If we could, through the development of a real system of highways, reduce the operation cost of motor vehicles i. e. per mile (and we can) the annual saving to motorists would be \$560,000,000. This capitalized at 4 1/2 per cent would represent an investment of about \$12,500,000,000. This could be proved to be a profitable outlay on this one item of saving alone.

We must brush our brains clear of cobwebs, obsessions, prejudices and bunkum, and calmly recognize that when we bought and insist upon operating fourteen million or more motor vehicles, we bought also a highway expenditure of billions of dollars, just as much a part of the cost of these motor vehicles as are themselves, their tires, their engines, and their supplies. They go together, the motor vehicle and the highway on which it must run. All the costs must be paid.

A. R. HIRST.

Valuation Taxes—We believe that there should be a valuation tax upon motor vehicles if there is to be a valuation tax upon any class of property. Of course, if the theory of collecting taxes upon the basis of the valuation of property is wrong, then a valuation tax upon motor vehicles is wrong. Vice versa, if the valuation theory generally held is right, then the collection of a tax based upon the relative valuation of motor vehicles is right.

The more expensive automobiles are owned for the same reason that the more expensive homes are owned: that is, because the owner believes that they repay him for the added investment and the added running expense in style, comfort, economy and convenience, or in the ability of himself and his family to enjoy life. If he really believes these things are true, he should be willing to pay an additional price to own and operate the more expensive house or motor vehicle. It should be recognized, however, that a valuation tax on motor vehicles is not a highway tax but a property tax.

Horsepower Taxes—Many states license motor vehicles upon the basis of horsepower. We can think of no physical attribute of a motor vehicle which bears so little relation to its destructiveness as does its horsepower. Horsepower bears little or no relation to the speed, the weight, the value or the use of a motor vehicle. There are at least thirty-two passenger car models on the American market which have the same or less horsepower than the Ford. These thirty-two models weigh from 1,600 lb. to 3,500 lb. and retail at from \$500 to \$2,500.

Licensing by Weight—This system somewhat classifies the relative destructiveness of various cars as between themselves, and of motor trucks as between themselves and as distinguished from automobiles. Weight has also some relation to value, but only when the vehicles are new. If there is to be a graduated classification of cars for the purpose of licensing them, their weight is the best factor. We believe there should be such a classification.

"Police Power" Licensing—This is a necessity. The cost of the license plates, licensing and of proper motor vehicle policing should be included in the weight license fee and collected at the same time.

Franchise Taxes, Wheel Taxes, etc.—Some states still permit units of government smaller than the state to make charges upon motor vehicles in addition to taxing them as personal property. We believe that such charges should not be allowed to be made but that the full charge for the use of highways should be imposed and collected by the state. Outside of the debatable federal luxury tax now in effect, we believe that the federal government should not tax motor vehicles.

The amount which the motor vehicle owners should pay for highway service is a thing individual to each state. It should be determined upon by the legislature of the state as a result of the most mature deliberation. Simultaneous increases made by several units of government might, if permitted by law, seriously embarrass the motor vehicle owners and the motor vehicle industry.

The states are the best and should be the only collectors of imposts for highway service made upon motorists. If the division of responsibility for the main highways is such as to make it advisable, there should be distributed to the counties a part of the proceeds. The state and county highway programs in every state should and will consume all that the motorist should fairly pay toward the highway program. The lesser units of government, such as townships, cities, and villages, should be content to see the state and county taxes on property for highways reduced by larger collections from motor vehicles. This will enable them to increase their charges upon property for strictly local purposes, including local highways.

The sum which can fairly be collected from motor vehicle owners has a maximum. If the federal government takes a share and the local municipalities take a share, the state and county share will be so much the less. Necessarily the state and counties must make up the deficit by imposing direct taxes upon property or by taking a larger share of income taxation. This simply complicates the situation without changing the final result as to the total taxes paid by the various classes of property.

Motor Fuel Taxes—The motor fuel tax, commonly known as the gas tax, in our opinion is by far the most scientific impost upon motor vehicles. It meters highway service and the benefits received from the use of highways. It approximates toll gate results without the infirmities of toll gate procedure. The consumption of gasoline varies with the weight, the speed, and the mileage of the motor vehicle. No other factor in the car's domestic economy reflects so closely the benefits received from highway use.

It has been suggested that a tire tax would be just as good as a fuel tax. This might be true if it were not so easy to mail or ship tires, but we fear that if a tire tax were in effect the business of every tire dealer would be with people of other states. This would yield no revenue to anyone. On the other hand, gasoline is bought usually from day to day, is best bought in that way, and can thus be handled more cheaply and more safely than if shipped and stored for individual use.

Objection is made that the worse the road, the more fuel consumed, and the more tax paid. This objection cannot be met by any argument which we can devise except that as highway construction proceeds, the mileage of road that this objection applies to will become less and less. It is the only practical objection ever urged against the fuel tax, and objections equally valid can be urged against any tax ever in effect or ever proposed.

States can adjust ad infinitum license fees fixed by the horsepower, weight or valuation of motor vehicles, or by any combination of these factors. They can probably attain some fairness in the relative fees to be paid by the different kinds of cars and trucks. It can be determined that a Ford should pay so much, a Cadillac so much, a five-ton truck so much. The relation thus established between them may be fair. But how about the relation between the Ford which travels 2,000 miles and the Ford which travels

15,000 miles—the Cadillac which travels 5,000 miles and the Cadillac which travels 40,000 miles—the five-ton truck which travels 5,000 miles, and the one which travels 25,000 miles?

If the relative use of railways by various motor vehicles is to be included as a factor in determining the highway tax to be paid by the motorist, then the motor fuel tax must be in effect as one factor in the total imposts. It is the only practical way to collect impost which marks relative highway use and the relative benefits therefrom.

We believe that many states will find it necessary, at least during the coming heavy construction period, to impose fuel taxes of about five cents per gallon. States which have been extremely backward in highway development may have to collect as high as ten cents a gallon. We believe it will be usual to exempt fuel used other than in highway transport from paying the tax. This will cause some abuses, but there are abuses in every tax system. As soon as motor fuel taxes of quite uniform amount are in effect in every state, practically every objection to the gas tax will have been eliminated, and a method of highway taxation and of highway financing will have become universal which is as nearly in accord with the equities in the case as human ingenuity can devise.

How Chicago's Asphalt Pavements Were Examined

Methods Used in Critical Study—Trucks Carrying Cutter "Gun" Replaced Hand Cutting—More Rigorous Inspection Recommended

BY PAUL E. GREEN

(Consulting Engineer, Chicago)

BECAUSE of widespread newspaper accusations of faulty work the finance committee of the city council of Chicago determined in the spring of 1923 to investigate pavements laid in 1922. The writer was employed to do this work and a fund of \$40,000 was provided. Nearly 1,000,000 sq.yd. of 1922 asphalt construction was sampled and laboratory tests were made of the samples. The methods employed in the examination had to be developed and present some points of novelty.

The investigation showed that in general the full amount of material specified was furnished and that there was too great a variation in workmanship and probably some carelessness both in workmanship and inspection. A variation of 33 to 50 per cent was not uncommon in the thickness of the surface and in some cases the variation was 100 per cent. Where such variation was found it was noticed that the surface was not smoothly and evenly rolled. Much of this variation in the top was due to an excess or deficiency in the thickness of the foundation, though it was rare that the thickness of the pavement, both base and wearing surface, collectively and individually was not close to the specification requirements.

The first equipment furnished by the city for the work consisted of a gang of four laborers and a foreman, with hand cutting tools, a team, driver and portable asphalt repair wagon. Samples 12 in. square were taken for approximately each 2,000 sq.yd. of pavement, and for each three samples of surface a test hole was made through the foundation. Observations were made as to the surface of the pavement, the curb, the grading, the drainage and all other items which enter into the construction of this type of engineering work. All measurements as to thickness were made with calipers.

It was soon demonstrated that the taking of complete samples by hand was a very slow process and uneconomical. Nor could the necessary repairs (which were made immediately after the sample was taken) be made to advantage. Too much lost time resulted and not rapid enough progress was made. About the best that could be done per day was fifteen cuts, of which five included the concrete foundation. The average was less. In addition, as the work was started in early spring, the asphalt top was so hard, frequently containing frost, that the cuts chipped badly and in order to get a good sample it was necessary to make a large opening. This meant more material for repairs, more labor in handling the samples to the laboratory and exhausted laborers. Since the cuts were so large, the repair could only be called a temporary one and would later in the season have to be replaced by a permanent patch as part of the regular maintenance program. As all such work was presumably to be charged against the fund provided for the examination it soon became evident that a more efficient method was essential.

Use Cutter "Guns"—The bureau of streets as a part of its regular equipment has several trucks equipped with compressors which operate automatic cutter "guns." Each truck has four guns which work like a riveter. One of these trucks was secured. This outfit immediately expedited the work about 50 per cent and in addition enabled the gang to secure small uniform samples. The principal trouble then was that the repair part of the gang (equipped with a horse-drawn repair tank) could not keep up. Much time was lost in transporting the material for the mix, and in moving from day to day the "camp" or tool box of the gang. It should be kept in mind that the examination included many contracts scattered widely over 200 square miles of territory and that under the best of circumstances much time was lost in moving from job to job. Up to this point all repairs had been made by hand mixing of "black base," or in effect binder, for the foundation cuts, and a crude top mixture for the surface.

Three permanent asphalt plants of large capacity, owned by the city, are located at strategic points to cover the entire city. Only two were operating at the time of the examination. In a territory of this area (200 square miles) with approximately 3,000 miles of paved streets, the location of the plants meant that the haul from the plants to the point of examination might be 10 or 12 miles, an impossible distance with horse-drawn apparatus, but perfectly practicable for a truck. In order then to expedite the tests, it was determined to try the experiment of loading a regular asphalt construction truck with hot top mixture at the plant about 9 a.m., keep it well covered, and hope it would stay hot until the last repair was made about 3:30 p.m. The labor gang, reduced to two men to operate the cutter, would start at 8 a.m. on the street, proceed steadily ahead and the other two men with the asphalt truck would follow, starting about 1½ hours later and catching up by the end of the day. This scheme worked well. The number of cuts made increased to an average of twenty-two instead of twelve per day. The repairs were made in permanent shape and the hard manual labor reduced materially. The "hot stuff" stayed hot, the only difficulty being that on account of the small amount actually used in making the repairs there was considerable excess to dispose of each day and this was not

always an easy matter. That part of the problem was solved by putting the mixture in a barrel at the plant instead of taking a load, thus reducing the quantity, but keeping it at a better temperature and eliminating waste.

Base Sampling—Cutting the foundation so as to obtain a laboratory sample suitable for crushing presented many difficulties. It had been determined that the best method of investigation would be to secure small cubes of the concrete, crush them, and from new aggregate to prepare a similar laboratory specimen for crushing after 28 days. This prepared sample would furnish a measure for the field sample, and while it was not the thought to compare field and laboratory samples directly, it was considered that properly plotted curves could be made which would show very clearly the variation in the character of the work. A quantitative analysis to recover the cement was not deemed practical.

Cutting was done with an automatic bull-point drill. It was felt that a large 4-in. core drill would best do the cutting but none could be secured in time for the work. This part of the investigation therefore was not complete and observations could only be secured along general lines.

Much new information was obtained. One of the most important facts observed was that the subgrade was nearly always damp though all the streets were sewered. The foundation was often damp right through to the binder, indicating porous concrete and probably lack of careful mixing. Such a condition of moisture may account for some failures of the wearing surface.

Conclusions—The conclusions reached for Chicago conditions were as follows:

1. Extensive studies should be made of subgrade moisture of our city pavements, even when apparently adequately sewered.
2. The fine grading of the subgrade should be done to a templet to get the best results.
3. The same provision should apply to the concrete foundation.
4. The top surface would be much more uniform and smooth if the recommendations under 2 and 3 were carefully observed, and thus tractive effort reduced and the life of the surface increased.
5. Extreme care must be taken to seal the surface at the gutter, and at manhole openings to prevent the ingress of water. The junction of the concrete gutter used in Chicago, with the asphalt surface should be redesigned to make a more positive seal.
6. A city having a large yardage of asphalt should be provided with a core-drill testing machine and no work accepted until it had been tested by such a machine. The samples should be kept as part of the record.
7. The quality of the work would be improved if samples of the foundation for crushing tests were made at the time of construction. These samples should then be compared with core-drill samples taken under 6.
8. There is danger in large cities of the work and specifications becoming too standardized and inspection too routine. The inspector on the job must be carefully trained and kept "on his toes." At least two daily visits from a supervisor are necessary. Inspectors should be placed with the grading gang and the sewer connection gang and that division of the improvement scrutinized with the greatest care.

Through the Reclamation Country

By F. E. Schmitt
Associate Editor, *Engineering News-Record*

THIS is the eleventh of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

The series of letters began in the issue of October 4.

La Junta, Colo.

ACHEERFUL pessimist remarked a few weeks ago that irrigation finance is a skin game, which in past years cleaned out one or more crops of trustful investors, and since then has been waiting for a new crop to grow up. He also intimated that this new crop seems to be about ripe. Right or wrong, his remark ties up curiously with a number of conditions and developments in the arid West, all bearing on the future of irrigation, private as well as federal.

Future Private Irrigation—The era of public land reclamation as contemplated in the 1902 act of Congress seems to be about over; irrigable public land in bulk is gone. The amount of fertile land in the West far exceeds the available water, but virtually all remaining land is privately owned. This seems to mean private irrigation enterprise, or else a new reclamation policy. The future work will be at a disadvantage, however. While less than half the available water has been used, the rest will be very costly to impound and spread over the land. All the reasonably favorable irrigation projects have been exploited. Land promoters have combed them over, and the federal people have done the same, in some cases even more anxiously, since the law obligated them to find a project in every western state whether or no. In consequence we are now right up against high-cost projects, developments whose per-acre cost goes far beyond even those costs of existing projects which have been declared by the farmers to be impossible of payment.

At present, we are told, those reclamation projects which cost more than a certain sum per acre (say \$75; people differ on the figure) cannot in general pay a higher construction installment than 4 per cent; the farmers balk at the 6 per cent installment which under the twenty-year repayment law must be made in all years after the sixth. Since the farmers do not have to pay interest to the government, it follows that private enterprise could never get even its interest. Yet there is a considerable activity in irrigation promotion in the West just now.

The investing public is hard-boiled, of course. It needs to be convinced that irrigation securities are good. Having been taken in on irrigation bonds in past decades, and more recently in other doubtful investments, it now desires to be shown. Means have therefore been provided to show it.

State Endorsement—Most or all of the western states have passed laws providing for state approval of irrigation plans. When a project is approved it is "certified" by the state. This is supposed to reassure the investor. It may reassure him, but whether it gives

any real assurance that his money is soundly invested is open to question.

More than thirty years of irrigation enterprise have shown by the loss of many millions of investment that a good design for an irrigation system will not automatically pay interest. Neither will well-built works. Settlers must come and use the works; they must be good farmers and must build up a profitable farming business; and they must keep this business in permanently sound shape, fighting off seepage, blight, and grasshoppers. Unless such a successful farming community is built up, the mere irrigation works are dead property, even if the state built them. It may take many years to build up such a community, and the project meanwhile may fail; yet, blandly disregarding this risk, the states now attempt to say, in effect, that the investor may safely put in his money, on the strength of state examination of the mere plan.

Some states have made the reassurance stronger. Oregon has recently passed a law which permits the state to guarantee the interest on irrigation district bonds for part or all of the first five years, and under this law the state now pays such interest. To the intending investor it will surely seem good to buy bonds whose interest is guaranteed by the state. However, after the first five years he will have to look out for himself. An Oregon land banker expressed decided doubt whether all the new districts would be on a profitable footing after five years—in other words, whether their bonds would be good after that time. Meanwhile the bond broker has further jeopardized the success of the project by pocketing 15 per cent of the bond proceeds. *Caveat emptor!*

Still another step has been taken by Oregon's northern neighbor. Washington has a new law which sets aside a certain amount of money each year for state purchase of the bonds of irrigation districts. This makes the securities still more attractive: they are so good that even the state invests its money in them! But just how such state investment will make the successful agricultural development of a project more certain is not obvious.

Another curious side to the matter of private irrigation development enters the case. Land may be made less valuable by the construction of irrigation works than it was previously, at least as concerns loan values, which in some way are a measure of actual values. This sounds paradoxical, but it is the statement of a land banker, and is explained in this way: Suppose a piece of unirrigated land suitable for at least some use is worth \$20 an acre, and on the 50 per cent basis has a loan value of \$10 an acre. If irrigation works are constructed at a cost of \$80 an acre, which cost is a lien on the land, then the equity or loan margin is still \$20 per acre, and again on the 50 per cent rule a loan of \$10 might be made. But this loan would be quite unlikely to be made, as the banker would consider the \$80 lien so heavy an incumbrance as to make it unsound practice to risk a further loan, the more so as this would be a secondary loan. In other words, the man who could get a \$10 loan on the unirrigated land could not get any loan on the irrigated land. The irrigation improvement thus has resulted in a temporary reduction of value, a loss which is restored only when the land is in successful agricultural production. The condition noted, of course, tends to increase the already serious financial problem of irrigation.

State Irrigation—But, to take a more optimistic view, there is a strong hopeful element in the situation. If the state certification and guarantee laws mean anything, they mean that the western states have begun to recognize the fact that there is a state responsibility in irrigation development. For the present this recognition is painfully weak, but in time it may grow to the point where the state realizes that the whole irrigation problem is its own problem, and proceeds to undertake settlement and agricultural development and the financing of the new settler through his start-up period.

Up to the present we have continued to think of irrigation development as a proper field for private enterprise, just like starting up hat factories or iron foundries. Some of the wisest people in the West seriously doubt whether it is a private function at all. A senator of broad outlook made the penetrating comment on the whole subject of irrigation, "There is no room for a middleman between the farmer and the water." In other words, as hundreds of cases have shown, a corporation that undertakes to supply irrigation water to the farmer and make a profit out of the transaction is very likely to meet disappointment, incidentally getting the farmer into trouble also, in many cases.

Irrigation districts are thriving by virtue of this truth. They represent direct water service, without profit, and they also are a device for bringing the problems of the water user and of the water distributor into direct co-ordination. However, development of vacant land can not well be done by the district method, and this field needs to have some other method devised. Just at present it seems as though the state must supply that method. This statement, however doubtful it might otherwise be, has the solid backing of the success made by California in its development work at the Durhara and Delhi settlements. The state showed there that the problem of settling up an irrigated tract with capable settlers, and giving them so effective a financial start that the early operating loss is reduced to very small proportions, can be handled by the state in a way that neither private enterprise nor federal organization could match.

More Reclamation?—There are those who say that federal reclamation ought to be continued as actively as during the past twenty years, and there are those who say that agriculture is heavily over-developed. The latter seem to be in the majority. One authority states that California's irrigated land is 40 per cent vacant, and these conditions are not peculiar to California. Low prices for agricultural products tell of over-production, a supply exceeding the consumption, so that under present conditions, where an elastic market is lacking, the farmer loses in the bad years because he has nothing to sell and in the good years because he must sell below cost. Such conditions do not represent a natural demand for development of more farms at high cost. Above all, they do not afford a very good argument in favor of the wholesale development of farming regions ranging from 100,000 to 1,000,000 or more acres, such as various promoters have been proposing.

Very likely, federal reclamation in its beginning was the answer to an urgent need for making western arid lands fruitful on a basis of sound planning and a square deal. Today there does not appear to be so

urgent a need for the nation's intervening in these problems of local development. However, precisely this is the central point of the reclamation policy that Congress is bound to lay down for the future.

Justifiable Cost—If Congress will have to say under what conditions there is an economic justification for the nation to reclaim more western land, it is also partly up to Congress to say how the justifiable cost of irrigation development is to be fixed. At the moment the situation seems to be deadlocked. Reclamation has been carried on with increasing cost of development to the point where the reclamation farmer says he can't pay even the interest on the cost. In fact, this claim is made even on projects where the costs are well below the maximum. How, then, can still more costly reclamation projects be warranted? This question finds no answer. Or, rather, there are three answers, which do not agree at all.

One answer is that by proper methods the conditions can be made favorable for high production, and the operating loss of the early years avoided, just as at Delhi the state of California makes the farmers' business pay even though the land and water alone, without farm development, cost over \$200 an acre. Of course, this implies much control, to get good farmers, well developed farms, and efficient farming systems. Men who do not favor such control but prefer the normal go-as-you-please type of development, have a different answer: that the demand for farm products is bound to increase steadily, until in a few years the demand will exceed the supply and agricultural incomes will rise to the point where they can pay even the largest development costs yet contemplated. The third answer is that it does not matter whether the land can pay for the irrigation works; making arid land fit for settling and home development is so inestimable a public benefit that the nation (I have never heard the argument applied to the state) can afford to invest almost any sum in irrigation, even without hope of return.

Whether the national-benefit plea has any force or not, certainly so far as private irrigation development and local development are concerned the question of justifiable cost of development must be answered in convincing figures. The land promoter or the district cannot afford to go ahead without at least a fair chance of getting the money back out of the soil. Perhaps the land promoter does not care so much whether the soil will pay, so long as he can make the prospects look rosy enough to intending buyers so that all his land will sell. But a district, or a state which morally or financially underwrites irrigation securities, must figure more carefully.

So far as the facts give a clue to the answer, they are that much promotion of irrigation development is now in progress which bases on unit costs of \$100 and more, though no such developments have yet gone through the financial test; and, on the other hand, that the federal reclamation projects, with lower costs, are claimed to be incapable of paying out. Probably the West will have to take the lead in reconciling these conflicting facts. Congress cannot be expected to do so by decree. But it seems clear that Congress will have to lay down some guiding principle by which any further federal reclamation that may be undertaken can be selected and planned consistently. If this principle is clearly enough stated, it ought to be of great

help in making the basis of private irrigation investment more sound than it seems to be at present.

Many Irrigation schemes—Just why the West should be full of new irrigation schemes under present conditions, when agriculture is not on a paying basis, is not clear. Possibly the general boom spirit of the West, its desire to develop, is the motive impulse. The fact is there are very many schemes for new irrigation, and most of them seem to revolve around the expectation of getting money from the federal government. This makes them of direct interest to all parts of the country at the present juncture.

Some of the schemes concern new developments of ambitious character. Most notable of these, of course, is the Columbia Basin project in Washington, where it is proposed to irrigate 1½ million acres at \$200 an acre (the figure is somewhat in dispute). Nearly as ambitious is a Utah scheme which aims at development of the full possibilities of the Great Salt Lake basin. And there are plenty of others.

Invariably the federal pocketbook is expected to furnish the funds. It is not easy to tell whether this is because the state cannot raise the money, or because the state is unwilling to risk its money and take the chance of loss. If the undertakings can be shown to be profitable, the state ought not be financially timid; and if they cannot be shown to be profitable, is the investment any more attractive for the nation than for the state?

Besides these new schemes, there are many existing irrigation projects that have gotten into difficulties and want government help—"lame-duck projects." A few of these have already been forced on the Reclamation Service and others seem to be going the same way. As a result, there is a chance that reclamation will not be able to make as good a financial showing five years from now as at present. And there are still other cases, such as getting the government to build irrigation works for a Nebraska district that already has plenty of water. In short, the desire to get federal money to put into western irrigation continues to be as strong as it ever was; if anything, it is getting stronger. And as matters stand there seems to be no established principle, whether in the reclamation law or in the western mind, as to how and when an irrigation investment by the government is worth while. Some people seem to think that any federal money that can be obtained for any irrigation scheme is good money.

It would obviously be of the greatest help under these circumstances to have a sound workable basic principle laid down by Congress to guide future reclamation investment—for example, the principle that every project undertaken must be able to pay its keep.

But even before such a principle is established the question ought to be considered to what extent land irrigation is a federal function. The complicating factors of interstate and international water rights affect some cases but not all. Conditions that twenty years ago made the western states unable to do reclamation work of their own are probably no longer present. Reclamation as it exists today seems to be a kind of business, like running railroads or ship lines. It seems to be accepted doctrine that the federal government ought to keep out of business as far as possible. Ought it keep out of reclamation?

Water-Curtain Fire Protection of Union Central Building

A WATER-CURTAIN system for protection against outside fires has been installed on the tall office building of the Union Central Life Insurance Co., Cincinnati. It represents a direct result of the disastrous Burlington Bldg. fire in Chicago, March 15, 1922, when a modern sixteen-story office building of so-called fire-proof construction was completely gutted by fire entering from burning buildings on the other side of the street. Pumping tests made of the Union Central Bldg. installation during a two-hour period on Nov. 18 showed it to act very effectively in covering the exposed sides of the building with a flowing sheet of water protecting it further by a curtain of finely divided falling water or mist. A picture taken of the water curtain in operation on the south and east sides of the building is reproduced as Fig. 1 herewith.

Two sides of the Union Central Bldg. front on streets. The west side directly adjoins a seven-story building, while the south side is separated from adjoining buildings by an alleyway (Baker St.). Protection was considered necessary primarily on the west and south sides, but the two rows of windows next the north and east sides were also protected. The installation comprises an open sprinkler or nozzle in the middle of the head of each window, facing down and inward toward the window; the sprinkler openings in the upper part of the height are $\frac{3}{8}$ in., those in the middle part, $\frac{5}{8}$ in., and the lower ones, $\frac{1}{2}$ in. Occasional windows or tiers of windows are omitted. As indicated on the diagrammatic perspective, Fig. 2 herewith, the system extends from the 17th floor to the 3d on the south side of the building, and to the 9th (roof level of adjoining building) on the west side. The two

FIG. 1—WATER-CURTAIN IN OPERATION

South side of building (left) fully equipped; east side of building (right) equipped on southerly two rows of windows.

adjoining rows of windows on the east and north sides are protected from the 17th floor down. The total number of sprinklers is 291, there being 148 on the west side, 93 on the south side, 30 on the east side, and 20 on the north side.

Normally the system is dry. Water enters the

FIG. 2—WATER-CURTAIN EQUIPMENT ON WEST AND SOUTH SIDES OF UNION CENTRAL BUILDING, CINCINNATI

No protection was considered necessary on the north side of the building, which faces Fourth St., and the east side, facing Vine St., except on the two rows of windows adjoining the exposed west and south sides. The south side of the building (right front in diagram) faces a narrow street or alley and is fully protected by water-curtain.

sprinkler pipe system only when the sprinkler pumps in the basement of the building are started. These are a steam pump capable of providing 750 gal. per minute and an electric pump of 1,800 gal. capacity, both working against 150-lb. pressure. The steam pump is the fire pump of the building, and the sprinkler connection is additional to the building standpipe connection. The electric pump serves the sprinkler system alone, and being located 12 ft. above boiler-room level it can be kept in operation even when the boiler room is flooded; however, this electric pump also has a suction connection for draining the boiler room when water enters the latter. Besides the pump supply, the sprinkler system can be supplied by fire department pumps from two 6-in. steamer connections outside, equipped for eight 2½-in. hose connections. Street connections as well as pumps discharge into an 8-in. riser pipe extending up to the pipe gallery floor (between the 16th and 17th floors), where the water is taken by a header distributing to six 4-in. vertical feed pipes on the outside of the building, supplying the sprinkler branches direct.

The outside piping (5,000 lin.ft.) is extra heavy galvanized wrought iron, with galvanized fittings and

hangers; it is held by anchors set into the brick backing of the exterior terra cotta. It weighs 14,000 lb.

In the test the sprinkler system was supplied from the steamer connections. A full supply was obtained at the 17th floor, the highest sprinkler line, 250 ft. above street level.

Separate from the sprinkler system the Union Central Bldg. has three 6-in. risers for fire outlets with a 2½-in. outlet and hose on each floor. These pipes are supplied from a 3,000-gal. tank on the 30th floor (base of tower) and a 5,000-gal. tank on the 18th floor, and also have Siamese street connections. Standpipe and sprinkler systems are independent.

The decision to install this water-curtain equipment was due to the desire of the owners of the Union Central Bldg. to protect themselves against such an occurrence as the Burlington Bldg. fire. The insurance company occupies the 3d, 11th to 17th and part of the 18th floor, the latter housing the company's records. Investigation by Capt. M. W. McIntyre, manager of the building, indicated that wire glass supplemented by a sprinkler system would give the best exposure protection known. Wire glass will stand up until it melts at 1,500 to 1,700 deg. F.; but enough heat would probably be radiated through the glass to ignite combustible material inside the building. This led to the decision to adopt sprinklers for keeping down the temperature of the sides of the building where exposed to a fire and intercepting radiant heat. The installation was planned and carried out by the Grinnell Co., Inc., with check and supervision by the Underwriters' Laboratories. Assistance was given in developing the system by J. A. Hiller, superintendent of water, and B. J. Houston, chief of Fire Department, Cincinnati, and Capt. J. J. Conway, superintendent of the Underwriters' Salvage Corps in that city.

Automobile Accident Deaths Increase

The Department of Commerce has announced that according to the returns of the Bureau of Census there were 11,666 deaths caused by automobiles and other motor vehicles (excluding motorcycles) in the United States in 1922. This represents a death rate of 12.5 per 100,000 population for 1922 as against 11.5 in 1921, 10.4 in 1920, 9.4 in 1919, 9.3 in 1918 and 9.0 in 1917. The following list of cities of a population of 300,000 or over is arranged according to the 1922 rate:

CITIES	DEATHS BY AUTOMOBILE PER 100,000 POPULATION				
	1922	1921	1920	1919	1918
Los Angeles	29.5	27.1	24.1	21.1	16.8
San Francisco	22.3	18.1	17.2	16.9	15.0
Chicago	22.0	20.5	17.3	12.3	11.7
Pittsburgh	20.2	17.8	16.6	16.1	18.1
Buffalo	20.1	15.6	20.4	13.5	18.2
Cincinnati	18.8	19.6	14.2	16.7	14.8
Newark	18.8	16.0	18.4	19.0	15.3
Kansas City, Mo.	18.3	19.9	17.1	13.1	20.5
Detroit	17.7	13.4	17.2	14.4	13.7
Minneapolis	17.7	12.5	10.7	10.1	11.9
Baltimore	17.1	13.3	13.1	14.6	16.7
St. Louis	16.9	15.1	13.4	13.7	12.5
Boston	16.9	13.6	11.8	16.8	14.8
Cleveland	16.6	17.8	19.2	16.0	22.0
New York	15.3	15.4	13.6	14.0	10.7
Washington	14.6	12.1	11.3	13.4	15.1
Philadelphia	14.1	10.2	12.3	10.6	12.8
Indianapolis	14.0	12.3	11.3	8.4	8.9

Of the cities between 300,000 and 100,000 population, Youngstown, Ohio, has the most noteworthy record in having held the record for a high death rate of 30 in 1917 and 31.9 in 1918, and having had a sustained high rate until this year when it dropped to 20.4 per 100,000. Hartford, Conn., and Bridgeport, Conn., and Camden, N. J., have also had a high death rate during these years.

Chamber of Commerce Reports on Transportation

Regulation Through Administrative Agencies—Voluntary Consolidation—Readjustment of Relative Freight Rates—Co-operation Between Rail, Motor and Water Transport

A review of the reports to the Chamber of Commerce of the United States by five special committees appointed to consider various features of the

transportation problems of the country. The reports have been issued for consideration in advance of a national transportation conference.—EDITOR.

Public Confidence in Railroad Securities Should be Restored

CONTINUATION of private ownership and operation of railroads in the United States conforms with the American economic system, according to the Committee on Governmental Relations to Railroad Transportation, and the committee thinks that railroad regulation should follow the principle of protecting the public interest and preserving the advantages of competition under fair conditions, while at the same time seeking to give a fair return to capital and fair wages to employees. Both the federal and state governments should consistently follow the principle of regulating the railroads through properly constituted administrative agencies rather than by legislation dealing with specific problems such as rates, practices, and other matters involving railroad operation and management. The committee approves of the recapture clause of the Transportation Act providing for the return of one-half of the surplus above 6 per cent that any railroad may earn upon its capital invested in the transportation service of the country, but it is not convinced that the present requirements which provide for a rate of return of 5½ per cent upon the value of the railroad property is adequate. It points out that the railroad credit has been so impaired in the last few years that investments in railroads during this period have been mainly in bonds, equipment-trust and other fixed-interest-bearing securities until the proportion of such securities as compared with stocks has become dangerously large. This condition can only be corrected by establishing railroad securities on a basis comparable with like securities in other industries.

The committee points out the importance of restoring public confidence in railroad securities so that they will again be able to sell their stock to raise capital for enlarging and extending their facilities, pointing out that if the method of financing followed in the past decade through the sale of bonds and equipment-trust certificates is continued during the next decade most of the railroads of the country will be in a financial position whereby a sudden period of depression would throw them into bankruptcy. In this connection the committee points out that according to its estimate of the new mileage and capital requirements for the next decade (abstracted in *Engineering News-Record*, Nov. 29, p. 896) the railroads will need to raise \$8,000,000,000 new capital, exclusive of the capital required for grade-crossing elimination, automatic train control, and other safety provisions made mandatory by legislation.

As valuation is essential to the successful regulation of railroad rates, the committee recommends that the valuation work being carried on during the past ten years be completed at the earliest practicable date.

The committee feels that the arrangement whereby the Interstate Commerce Commission has both the power and the responsibility for rate regulation is a desirable arrangement in that it not only gives the commission power to suspend rates that it deems too high but also to raise rates when they are too low. It does not feel that there should be any change in the labor provisions of the Transportation Act, nor does it feel that there should be any changes in any of the important provisions of the act until it has had a fair trial which, at the present writing, it has not had.

* * *

Graduated Tax on Gross Earnings For Transportation Agencies

RADICAL changes in the method of taxing transportation agencies are recommended by the joint subcommittee of the United States Chamber of Commerce on Taxation of Transportation Agencies. The committee points out that the present method of taxing common carriers by ad valorem taxation is largely an attempt to apply the old general property tax, in use in the early days of this country for the taxation of land and simple personal property, to complex and widely distributed economic units, manifestly in form unfitted for such methods of taxation. As a remedy for this condition, it suggests a graduated tax on gross earnings depending on the relation of net to gross as recommended by the New York State Committee on Taxation and Retrenchment. The committee considers this method of taxation as sound in principle and recommends that it be applied to steam and electric railways and as far as practicable to motor vehicles when used as common carriers. Such a tax has the elements of a sound tax in that it has certainty, reasonableness, and simplicity, while at the same time the state in each case will be assured of at least some revenue from each corporation. The tax as applied to steam and electric railroads should replace the multiplicity of taxes at present levied upon them, including federal taxes on the capital stock and income, and the various state and local taxes, such as franchise taxes, (of different form in each state), ad valorem taxes, taxes on gross earnings and on capital stock, annual licenses, special franchises, local real estate and personal property taxes. The committee recognizes that there will be some difficulties in allocating this tax to the various political units, but believes that an equitable method of doing it can be devised. It also recognizes that under the diverse bookkeeping methods employed by the small companies and individuals, who comprise the bulk of the highway transport common-carrier operators of today, practical administration of a gross-net tax is impossible. Pending common-carrier regulatory control which will place the earnings of these carriers upon

a comparable basis for taxation, the committee believes that such increase should be made in the taxes now levied against common carrier motor vehicles as will bring the charges to an amount equitably proportionate to those that may be assessed against the other carriers. It recognizes that this recommendation segregates common carrier motor vehicles not only from private cars, which have no gross or net earnings, but also from motor trucks used as private carriers and not subject to public control.

The committee frankly accepts the motor vehicle as an essential addition to the transportation agency required in modern economic life. It follows that improved roads to carry these motor vehicles are equally necessary, but the committee draws attention to the fact that these highways must, of necessity, be free to the general public and built out of general public funds, while in the case of steam and electric railways the investment in roadway is a capital account and returns on this investment are paid out of income. On the other hand, the steam and electric railways have certain franchise rights in the use of their roadway. Since the motor vehicle derives a special benefit from the improved highway, the committee believes that it should bear the entire expense of maintaining these roads in as good condition as when they were built, even where this involves resurfacing or reconstruction of the same type of road. In addition to a maintenance tax, highway transport common carriers should pay a tax in exchange for franchise rights comparable to those owned by the other carriers. By the payment of such maintenance costs the motor vehicle puts itself on an equality with the steam and electric railways which pay for the maintenance of their own roadways through direct charges to operation instead of by taxation. The committee does not, however, believe that motor vehicles should be burdened with a special tax for the maintenance of secondary roads which are not suitable for motor use. Finally, the committee states that it would not be performing its full duty if it did not recommend that all possible influence be brought to bear to eliminate wasteful, extravagant, or unnecessary expenditures from the highway program, which should always be subject to centralized and co-ordinated administration.

* * *

Voluntary Railroad Consolidation is Recommended

THE FIRST step in railroad consolidation would, according to the report of the United States Chamber of Commerce Committee on Railroad Consolidation, appear to require the development of a practical basis whereby the twenty-two systems might merge and absorb their various affiliated leased and operated railroad companies and thereby round out their systems and eliminate hundreds of smaller corporations. This step would need to be carefully safeguarded so as to insure as a final result the proper financing and efficient operation of the large consolidated systems. The purpose of the Transportation Act was to encourage such consolidation, but certain provisions of the act have been interpreted in such a way as to delay such consolidation, while, on the other hand, further provisions enable one carrier to obtain control of other carriers either by lease or purchase of stock and yet specifically provide that such control must not involve

merging such carriers into a single system for ownership and operation.

The committee states that the purpose and method of the proposed consolidation of the railroads have been misunderstood by many persons. The mistaken supposition is frequently made that the weak roads are to be saddled upon the strong roads and are to be assisted by the more fortunate members of the railroad family. If this were the aim sought by railroad consolidation, there would be little hope of attaining it, nor would it be a justifiable one. The facts of the case are that the weak and strong roads are to unite upon a common footing—that of actual respective values. This will be done by financial readjustment and recapitalization on the basis of earning capacity. If the factor of net earnings and physical values is taken to determine the values of consolidated railroads, and due consideration is also given to such special circumstances as may obtain in exceptional cases, consolidation can be effected in such a manner as to protect the equitable interests of all the roads and to avoid imposing burdens upon any of them.

As the Transportation Act requires that further consolidations of railroads must be approved by and be in harmony with a complete plan of consolidation to be adopted by the Interstate Commerce Commission, the committee recommends that this plan be completed as early as practicable and every facility to that end should be afforded the commission if Congress adheres to this condition set by the act.

The committee also feels that although some of the advantages to be gained from consolidation have been exaggerated, yet the following advantages will be attained by its operation: (a) Development of a limited number of more uniformly strong and stable railroad systems giving the public better assurance of adequate and efficient service at reasonable rates and fares. (b) Simplified and improved rate regulation made possible through more uniformity in the strength and the traffic characteristics of the several systems in each rate district, and permitting more ready adjustment in accordance with the economic needs of the various sections of the country and classes of traffic affected. This will not, however, adversely affect the existing rate-basing points or the established principles of rate making. (c) Economies in construction, maintenance and operation which, while somewhat exaggerated, will nevertheless be important. (d) Improved car service with wider movement of cars on their own systems, a greatly lessened necessity of car interchange, and the utilization of more direct routes, better grades and shorter hauls. (e) Preservation of competition in rates, subject, as at present, to the limitations imposed by government regulation, and maintenance of competition in service or often the enhancement of competition through rivalry between systems of relatively equal strength.

The committee feels that a full opportunity should be given the carriers to consolidate by voluntary action as compulsory consolidation will involve so many constitutional questions and is such an intricate and involved proposition that it might hinder rather than promote consolidation. It also recommends that the proposed consolidated companies should preferably be chartered by the federal government. It is not, however, necessary to insist upon federal incorporation which might be regarded as undesirable by the states or by par-

ticular carriers that fear to lose certain valuable rights that they possess under their state charters. Indeed, the states themselves might lead the way by enacting liberal and uniform laws removing the difficulties and cost of consolidating the existing railroad companies.

Finally, the committee does not recommend any changes in the consolidation provisions of the Transportation Act at the present time, but it thinks that experience will indicate the need of supplementary legislation in relation to (a) joint ownership of lines, (b) exchange or re-issue of the securities of existing corporations instead of creating new consolidated corporations, (c) authority for dealing with minority stockholders, (d) exemption from taxes on security issues or exchange involved in the consolidations or mergers provided they do not exceed at par the par value of the existing stocks and bonds of the present companies, and (e) the creation of suitable agencies to promote and supervise the working out of consolidation.

* * *

Co-ordination of Highway, Rail and Water Transportation

TWO COMMITTEES dealt with the separate phases of co-operation between the rail, motor and water transport of the country, one dealing with the relation of motor transport and the railroads, and the other dealing with the relation of water transport and the railroads. The report of the committee on motor and rail transport was abstracted in the issue of Nov. 22, 1923, p. 862. Both committees think that if the transportation needs of the country are to be adequately met there must be co-operation and not competition between the three principal modes of transportation. In general, they are of the opinion that rail and water transportation can handle bulk freight to best advantage over long hauls and that motor transportation can be used to advantage between rail or water terminals and individual shippers, and for short-haul traffic in areas where there is not sufficient traffic to warrant the operation of a railroad. In effect, the motor transport should be developed as a feeder for the trunk transportation system. The committees also feel that by a proper adjustment of rail and water rates, and by the provision of proper facilities for the interchange of freight, water transportation can be used to advantage for handling bulk commodities over long distances in all parts of the country where navigable streams or artificial channels exist.

Augusta Unlikely to Get Channel to the Sea

Augusta, Ga., long has enjoyed water-compelled rates because of the potential navigation existing between Augusta and Savannah. Recently the carriers withdrew the low rates. This resulted in a visit to Washington on the part of a delegation urging the improvement of the Savannah River to the extent of providing a 5-ft. channel. Such a project was adopted many years ago. Under that project the securing of that depth was to be accomplished by regulating works. It is the opinion of the district engineer, however, that such works would not give a year-around 5-ft. channel. He is convinced that locks and dams will be necessary. The Board of Engineers for Rivers and Harbors heard the arguments of the delegation, but it was evident from the questions asked that they doubt that the volume of commerce will justify the cost of this improvement.

Herbert Hoover on the Railroad Problem

IN HIS annual report as Secretary of Commerce Herbert Hoover discusses the problems of rail rates and railroad consolidation in the following paragraphs:

The difficulties of reorganizing the railway rate structure so as to secure simplification and to give relief in primary products—agricultural, coal, etc.—by a fairer burden upon finished and LCL goods are almost insuperable until the different systems are possessed of more diversified traffic and until the weaker roads have been absorbed. The necessity to establish railway credit and finance on a broader foundation than sole reliance upon the issue of mortgage securities; the necessity of provision for common utilization of terminal and other facilities; the impossibility of providing adequate rolling stock and particularly specialized cars so long as the burden falls solely upon the strong roads; the difficulties of more definite control of car service to meet seasonal demands and routing; the insuperable problems of equalization in car interchange; the slow progress in standardization and maintenance of equipment—all point to the imminent desirability of early progress with consolidations.

The idea of protection against excessive railway rates through the maintenance of competition is now dead. We should therefore secure the largest possible benefits from consolidation into larger systems by securing consolidation in such fashion as will protect and advance public interest.

The urgent importance of the early consummation of consolidation warrants consideration of methods to expedite it. Under the present provisions for wholly voluntary action subject to the Interstate Commerce Commission, many consolidations are likely to be long delayed. The difficulties of negotiation between the members of the groups that will be established by the Interstate Commerce Commission; the complications arising from varying priorities of securities affecting the determination of terms of purchase by one railway line of the property of another; the unwillingness of some lines to acquire or to sell others; the questions of individuality; the difficulties of establishing by negotiation the relative value of one property to another; the necessity of holding capitalization within the limits of the actual property values; the complexities and conflicts of state regulation and laws—all these problems would find a great measure of solution if the consolidated systems were allowed federal incorporation and if after a lapse of some appropriate period for voluntary action the Interstate Commerce Commission were given authority to create definite organization committees for each system including representation from the public and the component roads.

It should be the duty of such committees to develop and perfect a plan of consolidation either through the exchange of securities of the consolidated systems directly with the security holders of the component roads or by some other method. I believe that under such auspices the security holders would be willing voluntarily to make such an exchange. If a minority should refuse, it would be entirely feasible to invoke condemnation and purchase of their securities for the consolidated systems at an established fair value. Such a method would permit the determination of the relative value of the different railways considering both the physical properties and the often lower total of their securities, and due account could be taken of future as well as present conditions.

The ownership of some roads or terminals jointly by two or more consolidated systems could be provided for, as there are cases where such a solution would be most advisable in creating more efficient transportation. The public interest could be safeguarded by limiting the total capitalization of consolidated systems to an amount not exceeding the physical value of the railways as determined by the Interstate Commerce Commission under the Transportation Act as of June 30, 1914, plus actual capital expenditures and deducting abandonments and depreciation since that date. The total capitalization of many of the consolidated railways would probably be less than the Interstate Commerce Commission physical valuation and certainly less than their present nominal capital.

Federal Land Reclamation: A National Problem

8. Faults of Reclamation Law and Practice, and Their Remedies

By THOMAS H. MEANS

Consulting Engineer; Cape Rand Means Co., San Francisco.
Formerly Project Manager, U. S. Reclamation Service

The Eighth of a Series of Articles on the History and Performance of the Great Government Adventure in Irrigation of the Arid Lands of the West

WHEN the Reclamation Act was passed in 1902, irrigation was being practiced in all western states, but in only a few places was it profitable to the builders of the works. In parts of California, in the Mormon settlements of Utah, in Colorado, and in other places irrigation was successful, but on the whole the results were discouraging in the strictly desert areas. Private capital invested in irrigation enterprises had not paid, though the estimated profits were large. In many cases the losses both to builder of works and to farmer were serious. Such were conditions at the time the federal government entered the field.

Accomplishments—The 20th anniversary of the passage of the Reclamation Act occurred last year. In twenty years the government has invested in 26 projects \$136,000,000, and has collected \$13,000,000. The farmers have harvested eight million acres of crops valued at \$528,000,000. In 1921 there were 31,462 farms in operation, covering 1,158,000 acres, producing \$50,000,000 in crops. This briefly outlines the accomplishments; but the measure of success cannot be given in acres or dollars alone.

The Act placed a fund in the hands of the Secretary of the Interior to be used in the construction of irrigation works. The land benefited was to bear a water right charge which was to be returned to the fund in ten annual installments. This revolving fund was expected to provide ample funds for future reclamation projects.

The objects of the Act, to provide homes, have been accomplished. A large area of land has been reclaimed, many farms have been developed and the reclamation projects today represent as thrifty a part of America as is found in any region of the West. The yields of crops and returns per acre are better than the average in the states in which these projects are located. The farmer on the project is a little more successful than the average farmer in his state.

Collection of repayments has been less completely accomplished. Early in the history of the Service it was found that the collection of money in ten annual installments was impractical. The class of farmers attracted to the projects had little capital and that was needed to pay living and development expenses until the farms became productive. Efforts to collect money resulted in appeals to set aside or reduce the payments. Various amendments were made to the Act until now the time has been extended to twenty years. Each extension of time or adjustment was made after an investigation by Congress. In 1922 the Service reported that 85 per cent of the moneys then due had been collected. As the time covered by the records of collections included the period of low agricultural prices following the war it is a record to be proud of. Few business ventures can show better results.

Some Handicaps—Yet there have been many places where more rapid advancement could have been made

under different conditions. Handicaps of various sorts delayed the administration of the Reclamation law. Some of these are inherent to government activities, others can be removed by intelligent action by Congress.

The law itself seriously handicapped the progress of reclamation. It was a most general law, containing few details and leaving management in the hands of the Secretary of the Interior. Washington bureaus have for many generations been operated upon the theory that anything to be legal must be specifically authorized in the law, and in the execution of a general law such as this the old officers, who usually advise the Secretary, found it difficult to depart from time-honored customs.

As examples: The Land Office with a hundred years of red tape handled all land matters and was many times a stumbling block in the way of businesslike administration. The Treasury Department, whose auditors were unaccustomed to ordinary business practices, was frequently shocked by being asked to do things in a direct and businesslike fashion. Many other bureaus, whose co-operation was required by the new and vigorous service, were horror-stricken to find an attempt being made to carry out a job in about the same fashion that any business man would do it.

But the most important handicap of all was the Secretary of the Interior himself—the man who is authorized by law to “perform any and all acts and to make such rules and regulations as may be necessary and proper for the purpose of carrying the provisions of this Act into full force and effect.” The Secretary of the Interior is a very busy man. He is seldom acquainted with the problems of the West. He was often not in sympathy with the activities of the young organization. He was usually inclined to listen to the man who complained of hardships and to think the hardships were caused by the Service. He seldom knew how to get facts which were unbiased. As a result the incoming Secretary often became convinced that something was wrong with the Reclamation Service and held back his official approval on many activities until he could have time to investigate the condition of affairs. This has resulted repeatedly in delays, and some of the most distressing incidents connected with the Service history are due to this one condition.

Garfield's Vision—One Secretary held a different view from the others. Secretary James R. Garfield, in Roosevelt's administration, had the belief that he was authorized by Congress to accomplish the purposes of the Reclamation Act and that anything required toward that end was to be done, unless it was specifically forbidden by law. His view, so directly opposite to the older departmental ideas, enabled the Reclamation Service to get a start in life and to establish the much needed precedent for later secretaries to follow. Perhaps no one man is more entitled to credit in the early days of the Service than Secretary Garfield.

As an example of his methods: The Land Office had decreed that there was no way of preventing settlement upon any reclamation project before completion of the ditch. The result was that settlers scattered over the whole project and often outside it, requiring the construction of canals and ditches of great length to supply small isolated areas of land. The Service had endeavored to open projects by units, so that settlement could be completed in one area before more distant lands were irrigated. It was only through Secretary Garfield's personal investigation in the field that this much needed reform was brought about. He directed the withdrawal of all land and the opening to entry of only such tracts as were ready for water. No new law was required to do this. The only thing needed was a secretary with the backbone to follow the recommendations of the Director of the Reclamation Service.

The State Apportionment Evil—The Reclamation Act provided for the establishment of projects in all sixteen western states, the intention being to expend the major portion of the funds arising from the sale of public lands within each state, within that state's limits. Within each ten-year period the expenditures were to be equalized to the extent of 51 per cent of the fund among the several states. In the border states in the semi-arid belt—North Dakota, South Dakota, Kansas, Nebraska and Oklahoma—the funds were large, and the opportunities for irrigation small; in an effort to comply with the law the Service spent a large amount of time and money to find feasible projects, but feasible projects have not yet been found.

This allotment of funds by states caused a great deal of political activity. The result is that we have now some projects which, though completed, have never been successfully operated. The pumping plants in North Dakota are examples of this.

"Lame Duck" Projects—Later in the history of the Service many projects which had been started by private capital were forced upon the Service in order to save struggling communities from extinction. In some cases these projects were afterwards made successful, in other cases success has not attended the efforts of the Service. As an example of the former, the Sunnyside tract of the Yakima River in Washington was taken over after fifteen years' effort on the part of the owner, the Northern Pacific R.R., at a time when both the farmers and the railroad were thoroughly discouraged over the lack of success of irrigation; the project has since become one of the most fertile and profitable in the West. On the other hand, in other states, projects taken over when on the road to failure have not succeeded. In these cases the Service was strongly urged to save the community and through political efforts forced to take over the completion and management of the project. There are today many other projects on which the farmers would be fortunate if they could get the Service to do likewise. These "lame ducks" should be regarded as evidence for, not against, the Reclamation Service.

In addition to these handicaps the farmer upon the Reclamation Service project was frequently no great asset. The announcement that the government was going into the business of irrigating lands and that there was a free home for every man in the West attracted the attention of all classes of people. The inevitable result was that many who were failures in

other walks of life and many incompetents flocked to the projects to take up land and reap the benefits of this munificent plan. Farming requires energy, skill and perseverance. Irrigation adds nothing to the ease of farming, in fact it requires a higher degree of skill. The quality of the settlers cannot be blamed upon the law; it can only be blamed on the inability of any governmental agency to select its settlers as would any private agency.

Administrative Errors—Handicapped as it was by the law and the precedent of Departmental rule, there is little wonder that the administration by the Reclamation Service was deficient at times. But the successes so far overbalance the failures that a fair-minded man finds little to criticize. It should be remembered that we are looking backward and in the light of events many things now appear clear. We see the reason why some things did not succeed. In other cases a turn in the tide has worked success out of a potential failure.

On the passage of the Act and organization of the Service there was a grand scramble for the money by all the western states. The end of the first year saw a fund of nearly \$5,000,000 available. Congressmen and politicians of other kinds besought the establishment of projects in many places. Attempts were early under way to have Congress direct the places where money was to be spent. The engineers were urged by those who knew the results of pork barrel appropriation to make the dirt fly. They did. Preliminary surveys made by organizations in charge of earlier investigations served to outline several possible projects, such as the Salt River dam, now the Roosevelt, in Arizona. Senator Newlands, of Nevada, had caused preliminary surveys to be made at his own expense of what is now the Newlands project. In the latter case a survey was at once commenced. In the Salt River Valley the land was so largely in private ownership that the organization of the land owners was necessary and that took time. Other projects were speedily outlined and the fund was allotted to keep it from being looted by promoters of questionable enterprises.

In its haste to nail the fund down, it is possible that the Service did not select the projects most desirable at that time, but there is no question but that it was necessary to allot the fund, for the mere sight of a pot of unattached money attracted too much attention. Throughout the history of the Service this has been true. At the present time there is an alleged eleven millions in the fund and many hungry eyes are directed toward it. The dismissal of Arthur Davis is in part attributable to the disappointed hopes of certain aspirants for the honor of spending this money.

Great difficulties of other kinds attended the selection of projects. Not so much was known about arid soils as now, hydrographic information was meager, we had little appreciation of the economics of agriculture in certain of our western valleys. Looking backward we now see that there was little chance for the farmer to make a success in certain western projects except by producing feed for cattle. The development of potato growing in Aroostook County, Maine, was a factor in making potatoes unprofitable in Idaho, but who could have predicted that twenty years ago?

The selection of projects was not left to a calm analysis of engineering facts. Influential citizens, big railroads and state senators often were a factor, as well

as soils, climate, water supply and market facilities. Certain Montana projects were strongly urged by Senator Carter while he was Chairman of the Senate committee on irrigation; transcontinental roads liked to have projects on their lines because of the increased revenues it gave them, and many and devious were the ways in which their wishes were made to come true. On the whole, however, the projects selected were such as would be successful. About the only project selected in which a mistake in engineering was made was the Hondo project in New Mexico, where the reservoir site, underlain by limestone and gypsum, was so leaky that it has never been filled.

There has probably never been any large undertaking so free from engineering mistakes. From being a beginner in irrigation the United States has become the world leader, and it is almost entirely the work of the Reclamation Service which has brought about the change. If any criticisms can be offered of the construction work of the Service it is that the work is too well done. There has probably never been any large public work, either governmental or corporation, which received so much for the money spent as the Reclamation Service. One reason for this is that the work has gone on long enough for a competent construction organization to have been built up. The newspapers now announce that the new plan is to go back to contract work. After twenty years' effort to build up an efficient construction organization, that is to be scrapped and a new method tried. Oh well, Uncle Sam is rich!

Faults of Management—Recent changes in the Service personnel by Secretary Work were made because he wished to place the management on a more business-like basis. He replaced a manager of twenty years' experience with one without experience, so far as one can learn from his past record. It is of interest to see what was lacking in the management of the business and what changes for the better are to be hoped for.

The reclamation law places the entire responsibility for the reclamation work upon the Secretary of Interior. He is, as we all know, about the busiest of cabinet officers. He selects the head of the Reclamation Service. Heretofore he has had little to do with the detailed organization, but all matters of policy must be approved by him. The executive head of the organization was the Director.

Under the Director were the appropriate legal and engineering staffs and on each project were engineering, construction, clerical and operating organizations. Administrative headquarters are in Washington, with engineering and operating headquarters in Denver. Management has to do with investigation, construction, settlement and operation of projects. At various times during the history of the Service changes in organization have been made; sometimes as the result of experience of the officers in direct charge, other times by the Secretary of Interior against the recommendation of the Director. As an instance of the latter, Secretary Lane placed management in the hands of a commission of which the Director was a member.

In the investigation preliminary to project construction, the Service has had the assistance and advice of the Department of Agriculture, the Division of Hydrography and other organizations which collect and digest facts. In the early days the information available was less reliable than now and on a number of projects we

see the results of this lack of information. For example, on the Newlands project large areas of alkali land were at one time thought reclaimable and ditches were built to water such areas. On the Klamath project an area of marsh land included in the original project was found to be of questionable value. Little money was spent on its reclamation, however. At Umatilla, Ore., an area of very light sand has been difficult to farm, though it is proving very fine land when once in crop.

Land examination was made of the projects early in their development. An effort was made to exclude all land of poor quality. Sometimes this examination failed to reveal the true character of the land and in a few cases the field examiners were overruled and land included which afterward proved worthless. Though mistakes of this kind occurred the area of land thus involved was very small as compared with the whole area, and the amount of money involved is but a small percentage of that spent. Such errors are common in any human endeavor; they occur in every enterprise, whether government, corporation or individual. There is now more reliable information about soils, water supply and agricultural possibilities of western soils, and future projects may profit by past experience.

Drainage—The difficulties caused by lack of drainage facilities are probably as often quoted as evidence of mismanagement as any other feature of our federal reclamation. Drainage problems accompany or follow irrigation nearly everywhere through the world. The reclamation projects have been no worse than most private projects. They should have been better. In the early days of project irrigation the lands seldom showed any signs of needing drainage. In some places the water table rose rapidly and damaged land before any remedy could be applied; in other places drainage was developed as fast as the need arose. The need for drainage arises where more water is applied than the land can absorb or the plants use; the greater the use the more necessary the drainage. Reclamation projects attempt to provide full service of water in all seasons, in other words, water is always available for use. Had the lands not had an abundance of water no end of criticism would have followed.

In order to be fair to the farmer water in abundance is provided. In this respect the Service has sometimes followed the easiest road rather than the best. Too much water is the greatest misfortune which can overtake an irrigated community. In fact what the farmer regards as enough water is generally too much. The greatest blessing to an irrigated community is a reasonable deficiency. With a deficiency the farmer is required to handle his water with more care and the results are better crops of better quality and less damage by waterlogging. It is less work to irrigate with careless methods—easier to apply a large amount than to spread just enough water uniformly. The water user likes lots of water so he can irrigate the easiest way, and as that is the wasteful way he wastes water.

The Service has done a great deal to encourage economic use. It has arranged schedules of prices so that excessive use is costly, and in other ways has tried to encourage economical irrigation, but it did not succeed until much land was already damaged. Many are inclined to censure the officials for this. A knowledge of the inside facts, however, shows the engineers in a constant endeavor to encourage economic use of

water. Lack of co-operation on the part of the water user was nearly complete. Nothing short of a kindly providence bringing dry seasons in a row has ever effectively taught any considerable number of American farmers economy in use of water.

The inevitable result of the wasteful use of water was a need of drainage. Drainage problems arose in many places. Usually the project was completed and the construction cost assessed to the land before drainage problems arose. No method of collecting money from the land was available and there was in some places a delay in getting drainage started. All of this has caused criticism of the Service. Congress could have corrected the matter at any time by appropriate legislation, which was recommended by the engineers of the Service.

Problems of Settlement—The success of an irrigation enterprise rests with the man who farms the land, not with the builder of the works or the operating engineer who delivers the water. The farmer makes success or failure. With good soil, a climate suitable for crops, a regulated supply of water and a market for produce, it would seem that the project could not help being a success. Such is not the case, however. The man who farms must know how to farm, must be diligent, hard working and businesslike. If any considerable percentage of the farmers does not have these qualities the success of the project is endangered.

Money is as essential as energy and experience to the farmer who takes up a reclamation farm. The amount depends upon the individual; it is the rare man who can succeed with two or three thousand dollars. Irrigation farming does not attract the man with money. Too many men without adequate cash have taken up farms on projects. There is no way for the government to select settlers. Any one with his homestead rights and enough cash to make a first payment can take on the responsibilities of making a farm out of a desert homestead. In the early days of government reclamation a land office fee of \$8 or \$10 was all the cash required. Secretary Garfield was persuaded that it was good business to require an advance payment of a year's water charges. This served to eliminate the man entirely without money, but it gave no assurance of future payments. The projects too often have been settled by men without adequate resources. This condition is not peculiar to government projects; all western colonization in recent years has suffered from this difficulty. This lack of funds resulted in many farms being slowly developed.

The time of payments to the government is set by the Secretary of Interior under the law. The settlers whose payments were due commenced an approach to the Secretary and Congress in hopes of relief. This advance took place in many forms and usually took place regardless of the ability of the farmer to pay. The small politician talked of it, and the larger politician asked votes on the basis of securing help for the poor farmer. The Secretary, hearing all of the noise about inability to pay (the man who could pay kept quiet) usually started an investigation into the real merits of the contention. Congressional committees went through the West to listen to protests from farmers on reclamation projects. In one case a questionnaire designed to bring out all complainants was sent out a few months ahead of the congressional in-

vestigating committee. The results of this agitation caused a general feeling that the farmers of the projects intended to try and get out of all payments. There is yet some doubt as to the real intentions or hopes of the average reclamation project farmer.

Farmers have had more help from the government than any other class of people. So many bureaus and experiment stations have been supported by the government in order to teach the farmer how to attend to his daily business that he has become a little self-conscious. Anything affecting his welfare is made the basis of political activity. The farmer on reclamation projects had no more need for consideration than any other western farmers. He had good irrigation works, a better regulated supply of water, and no interest to pay on his water charges. However, he has been led to believe that the money he owes to the government will be remitted or at least his payments will be delayed if he makes enough noise. He has never failed to make a noise.

It is really a wonder, in view of all this array of political, legal and administrative obstacles in the path of reclamation, that anything worth while was accomplished. The results speak for themselves and reflect great credit upon the qualities of the responsible officers of the Service.

A discussion of this sort adds little to our knowledge unless from it suggestions can be drawn for better practices in the future. The following suggestions are offered:

What Can Be Suggested for the Future

First of all we agree with Secretary Work that the reclamation policy must be placed on a businesslike basis. This does not mean the disruption of a valuable *esprit de corps* by the summary dismissal of a valuable man and a belated endeavor at fact-finding to determine why he was dismissed, but it means the following things among others:

1. Projects should be approved on the basis of their feasibility. Neither state lines nor political preferences should have any weight in the selection.

This has been the endeavor of the Reclamation Service at all times. Any departure from this rule has been caused by someone outside of the Reclamation Service.

2. Before final approval of projects, these things should be assured:

- a. Sufficient good land to stand the charge.
- b. Water supply unfailing in quantity and of good quality.

- c. Climatic conditions such that crops of value high enough to both support the farmer and enable him to pay his charges for water.

- d. Location such that freight rates permit the shipment of its products to an established market with fair returns to the grower.

- e. An economic need for the new agricultural area.

3. The charges for water should be assessed to the land in proportion to the benefits, not on a flat rate per acre as now.

This will permit the inclusion of poorer tracts of land which can be used for pasture or some other such use. The assessing of charges on basis of benefits will remove many of the inequalities which now result in abandonment of land.

4. The construction charge should not exceed a sum which the farmer can pay out of the proceeds of his farming operations. This charge should include interest upon the unpaid balance.

The lending of money without interest is the fundamental error of the reclamation law. There are today worthy projects, in regions where agricultural development is needed, which will cost more than the farmer can afford to pay. In such cases Congress should appropriate money for the excess, charging the farmer with the amount he can afford to pay.

5. The time of payment should vary with the project.

A California project may be able to pay faster than one in Montana. A period of no payment but interest should be required in the early years while the farmer's resources are required to bring his ranch into full development.

6. Settlers on public land and owners of private land should be required to show financial strength sufficient to place the farm on a paying basis.

7. Sale or transfer should only be permitted when the financial obligation to the government is completed or when the new owner is financially as sound as the former owner.

8. Operation and maintenance charges on unoccupied public land should either be paid by the government or added to the construction charge so no unfair burden be placed on early settlers.

9. All affairs connected with the details of project management should be placed in the hands of the farmers as soon as possible—preferably through Irrigation Districts.

10. Provision should be made for technical agricultural advice and co-operative handling of products through the Federal Department of Agriculture and state organizations. The farmers should help pay for this advice. Free advice like other free things is usually valued at its cost.

11. Endeavor should be made to cause the reclamation farmer to stand on his own legs, fight his own battles and, when hard times come, as they do to men in all walks of life, work out his problems as other men have to do. Blessed is he that doth not bellyache.

Relocation Avoids Large Trestles and Sharp Curves

LINE IMPROVEMENT and elimination of long and high trestles will be effected by a short stretch of relocation now in progress on the Algoma Central & Hudson Bay Ry., near Frater, Ontario. At this point (Miles 103.8 to 104.79) the line is about 750 ft. above Lake Superior and four miles from the shore of Agawa Bay, with two trestles spanning coulees high up on the range of hills which fronts the lake. A view of the big trestle is shown in Fig. 1.

FIG. 1—LARGE FRAME TRESTLE TO BE ABANDONED

Both trestles are of frame construction, built in 1911-1912. The larger one is 1,050 ft. long, and 75 ft. high, on a 12-deg. curve, with a central angle of 139 deg. The other trestle is 520 ft. long, 60 ft. high and mainly on tangent. Relocation for about one mile is being made to avoid the risk of filling such large trestles, but at the same time it will shorten the line by about 500 ft. and eliminate five 12-deg. curves, reducing the curvature by 201 deg. 42 min. This re-

FIG. 2—LINE REVISION ON CANADIAN RAILWAY

location is shown in Fig. 2. The grading will be mainly in solid rock, with three large cuts.

The contract for grading has been let to McNamara Brothers & Thornton, Sault Ste. Marie, Ontario. Track-laying will be done by company forces. It is expected to have the new line completed by June, 1925, after which the old track and the trestles will be salvaged. The cost is estimated at \$187,000. B. E. Barnhill is construction engineer in direct charge, while the work is under the general supervision of L. C. Maxwell, engineer maintenance-of-way, and R. S. McCormick, chief engineer and general superintendent of the Algoma Central & Hudson Bay Ry.

Irrigation in India

The total area of land irrigated in 1922 by all classes of work in India, exclusive of the Indian states, was approximately 43,125 square miles or 14 per cent of the cultivated area, according to a report issued by the Department of Industries and Labor, Government of India. The irrigation districts are distributed in twelve provinces. Extensions and new works are being made continually and hydro-electric projects are proposed in connection with some of these. Thus the Bhandardara dam to be completed in 1924, with a total height of 270 ft., will provide for 5,000 hp. and the Bhatgarh dam, 190 ft., to be completed in 1926, will provide for 3,000 hp. Both of these works are in the Bombay province. The estimated value of crops on all areas receiving government irrigation was more than double the total capital expended, while the returns on capital invested in productive projects ranged from 7.76 to 14.63 per cent. All of this work, both as to construction and operation, is under the Public Works Department of the Government of India.

Highway Officials Review Technical Activities of 1923

Papers and Discussions at New Orleans Meeting Stress Research and Administration—Construction Practices Get Second Consideration—Maintenance Neglected

Engineering News-Record Staff Report

PROFESSIONAL topics of unusual variety were reviewed in formal papers presented at the New Orleans convention on Dec. 3 to 6 of the American Association of State Highway Officials. These papers are here summarized under the heads of administration turnover, federal-aid, design and research, finance and construction. Incidentally, this grouping indicates the range of knowledge with which the modern highway commissioner and engineer must keep in close touch in directing the work of his department.

Administration Turnover—Charging the fault to highway officials themselves and to the inactivity of the association, H. G. Shirley, chairman, Virginia State Highway Commission, called attention to the dangerous turnover in department administration. In the last two years there had been a change in the directing personnel of 24 state highway departments. Road administration, construction and maintenance had advanced so rapidly that public thought had not kept pace. Failure to recognize this lag in thought and an attempt to force the pace and consequent antagonism of the public were the causes of many changes. Political interference was not a major cause. With ordinary firmness political interference in highway administration could be prevented by the department head. It was important to keep in line with public sentiment—to lead the thinking of the people, but not arbitrarily drive ahead with policies they had not been educated to approve. Once the confidence of the public was secured by leading and not by driving, its support could be had for any reasonable plan of highway development and political interference need not be feared. Education of the public had been backward.

Men who are capable of directing and handling expenditures running into approximately \$1,000,000,000 yearly should be of such a type as to command serious thought before any change in personnel was made. To handle so much capital there must be a stated term of office. This permanence of position was necessary to attract able and honest men. A change in the directing heads of 24 state highway departments in two years did not indicate such permanence of position. The fact that this turnover has not been protested indicated that the association was remiss in serving its members. Indeed, the fault lies in the fact that highway officials "have not brought to the attention of the public the great need and importance of continuous services for such offices in keeping with the offices of our railroads and other large organizations."

Interesting statistics of administration turnover were presented by H. K. Bishop, Bureau of Public Roads, in discussing Mr. Shirley's paper. During the eight years of federal aid, or from 1916 to 1923, 48 states have had 117 chief engineers of highway departments. Of these chief engineers 34 served one year, 35 served two years and 13 three years. The average official life of a chief highway engineer is approximately three years. Stated in a different way ten of the 48 states retained the same chief engineer for the eight years, 19 had two

chief engineers during this period, 14 had three, three had four and two had five.

Federal Aid—Selecting a federal-aid system of highways was reported to be substantially completed, by Thomas H. MacDonald, chief, Bureau of Public Roads, who gave credit to state road officials for remarkable co-operation. The officially-recorded road mileage of the country is 2,886,000. State systems aggregate 220,000 miles of which 80,000 miles are surfaced. In the past four years more miles have been surfaced than in all previous time. Withal, road improvement is lagging far behind traffic development. Completion of the federal-aid system in ten years calls for 11,000 miles of construction each year. Mr. MacDonald cited the need of extended traffic studies. There were needed uniform traffic regulations, more department testing laboratories, regular reporting of accidents, and better engineering inspection of road construction. Only 36 per cent of all road expenditures was provided by property taxes and only 11 per cent of all taxes were for roads. Only 40 per cent of the expenditures for roads was under state or federal control. Motor-vehicle license taxes and gasoline taxes should be for road improvement alone. Present expenditures, large as they seem, were small compared with the value received. Grade crossing elimination was a vital necessity. Of 753 eliminations on federal aid roads 62 per cent were accomplished by road relocation and 38 per cent by grade separation. Calling attention to troubles already experienced it was urged that no state should accept contributions for road improvement unless entirely without restrictions. For future practice, unstable sub-grade soils should be stabilized by adding some material as sand, gravel or cement. The outlook should be for a general raising of standards by research, more strict routine testing, better engineering inspection, better design and construction.

Calling attention to existing federal-aid funds W. C. Markham, executive secretary, noted the necessity for approaching Congress at the current session for action on the future federal-aid program if there were not to be a hiatus in federal-aid appropriations. It was pointed out that failure of states to take up their allotments of federal aid put difficulties in the way of getting Congress to adopt a federal-aid program of much greater size than at present.

Design and Research—Premising that research which which was not applied practically was of scant value, Charles M. Upham, chief engineer, North Carolina State Highway Department, described the development through experiment of the near-macadam roads and sand-asphalt roads of his state, in which there is a large mileage of top-soil or natural sand-clay roads. These roads have great strength, they will carry almost any load without breaking down, but they wear rapidly by abrasion and after traffic exceeds about 400 vehicles per day the maintenance, because of surface wear, becomes excessive. The problem was, when the excessive maintenance stage was reached, to retain the original

strength element and strengthen the surface to resist wear without going to hard pavement—that is, to provide an intermediate road between the original top-soil road and a paved one. Asphalt could not be applied to the old top-soil surface because a dust layer formed underneath and the asphalt peeled off. Also, it was observed that stone embedded in the old top-soil was held rigidly. Asphalt could be applied and would stick to the stone. Experiment was based on the last finding. The old top-soil was scarified and spread with one layer of 3½-in. stone which was rolled until embedded half depth in the loosened top-soil surface. Then asphalt, about 1.6 gal. per square yard, was applied and a layer of smaller stone spread and rolled. Finally, a light dressing of asphalt was covered with small stone and rolled. The result was virtually a bituminous macadam armor over the old top-soil road. These roads are standing up under a heavy traffic and their cost is half that of pavement.

The sand-asphalt construction is the result of another experimental study to utilize local materials. In certain sections there is only sand and no other material to be obtained except by extensive haul. The trial road was built as follows: The sand was graded and rolled with a grooved roller between timber side forms. An asphalt mixture of about 92 per cent sand was laid on the rolled grade and on this a surface of approximately sheet asphalt mixture. The cost of this type of road was less than half that of ordinary black-top roads.

Continuation of the Bates road test, using sections with thickened edges, was described by Clifford Older, chief engineer, Illinois Department of Public Works. These edge-thickened sections showed no failure under legal loads for 9-6-9-in. and 9-5-9-in. slabs, and no considerable damage under 13,000-lb. wheel loads. Several diagrams of repeated load tests 6 lb. per square inch in Illinois clay soils were exhibited.

Observations on tests and materials for concrete road construction by G. W. Hutchinson, of North Carolina, discussed by A. T. Goldbeck, Bureau of Public Roads, were presented in a series of diagrams too extended to be considered in the present report.

Finance—The tendency of recent legislation in regard to financing highway construction was reviewed by J. N. Mackall, director of the Department of Public Works of Maryland.

Salient features of Mr. Mackall's discussion follow:

The alarming thing about the recent tendency in the financing of highway construction and maintenance is the extent to which automobile license fees and the gasoline tax receipts are being used to finance relatively long-term bonds for construction. If the excess of receipts from the motor-vehicle user over the maintenance cost were used annually for construction, certainly it could not be criticised by any man. To do this is the best of business, but to issue bonds running over a long term of years, and set up as the first call on the receipts from the motor-vehicle user sufficient to pay interest and amortization on these bonds is insuring that the proceeds from the current receipts from the motor-vehicle user cannot be used for road maintenance as the need for road maintenance and reconstruction continues.

Many roads, in fact most of the paved roads today, are being built of concrete. The cost of maintenance of these concrete roads is a relatively small amount and will remain so for a number of years, but who will say that bonds running for terms of even 15 to 25 years will be retired before the best of concrete roads will require extensive reconstruction and maintenance. One of the greatest calamities which could befall the transportation program of any state

would be to find that there were not sufficient funds from current receipts to maintain in perfect condition roads previously built from bond issues or from current receipts.

It is fundamental that all maintenance and reconstruction be cared for from current receipts, and it is equally as fundamental that no prior charges be made against the prospective current receipts which could in any way prevent these current receipts from coming in sufficient volume to pay the maintenance charges on all the improved roads in the state. Representatives of the automobile industry have argued time and time again for the issuance of long-term bonds for road construction and at the same time have admitted that the responsibility for the maintenance of these roads was and should rightly be the responsibility of the user, but the greatest difficulty in this arrangement is the practicability of financing such a plan. If any community cannot raise with reasonably short-term bonds sufficient money for the original construction of its roads, that same community cannot in 10, 15 or 20 years become sufficiently prosperous to pay for the reconstruction of these roads from current receipts. If reasonably short-term bonds, say, on the serial annuity plan, fully matured in 15 years cannot be financed by a community from its general taxes, how is this same community going, in 15 years, to pay interest and amortization and in addition an annual maintenance cost much greater than this. Yet the automobilist has admitted and the automobilist does admit that it is his sole responsibility to pay for the maintenance and reconstruction of roads, and it can with considerable propriety be argued that this is the full measure of his responsibility.

Construction—Characteristic mid-western practice in gravel road construction was outlined by John H. Mullen, chief engineer, Minnesota Highway Department, as follows:

Gravel surfacing as practiced in the middle west is rather different than the methods of gravel road building prescribed in the text books. Trenching and the placing and rolling in layers of different sized gravel has been found to entail needless expense and a system has been developed which is in reality a combination of construction and maintenance, and consists, briefly, of spreading gravel on the roadbed and compacting it under traffic and maintenance. This sounds rather crude but it is a method which has been found to be the most economical after considerable experience in various systems of handling the work.

Subgrade is the first consideration and when bad sand is encountered a sand-clay crust is first built, or if the grade is composed of muskeg or unstable mucky material, a covering of clay is applied to sustain the gravel wearing course. The subgrade for graveling is bladed to practically a flat section with never more than a 4-in. crown on a 30-ft. roadway. Hauling is usually done with trucks, material being dumped in a ridge at the rate of 22 to 36 cu.yd. per station, depending upon the traffic to be served, the kind of gravel, and the material in the subgrade. The gravel is then spread with blade graders leaving not to exceed 3 in. in thickness on a width of 20 ft., the remainder being left in a ridge on each side of that width. Blading is then continued and traffic turned onto the road, a small amount of gravel being gradually brought in and moved across the roadway until a crust is formed by the traffic. In this way the surfacing is compacted from the bottom up without at any time having enough material in the travelled way to produce a loose driving condition.

On account of the great variation in gravels found in different parts of the state there is not a uniform specification for cementing values, wearing quality or grading of sizes; the only uniform requirement is that the maximum size of the gravel particles shall not exceed 1 in., which means that in practically all cases screening apparatus must be used. This is usually the ordinary rotary or shaker screen fed by a conveyor, but in the larger gravel hauling projects the material is generally loaded by a dragline or steam shovel through a "grizzly" or grate screen. To prevent oversize being hauled on the road it is required that the shaker or rotary screens have openings not more than 1 in.

in size but when grizzly bars or grates are used it is required that the bars or grates be spaced not more than 3 in. apart.

The state buys or leases the gravel pits, preferably on an average basis but when impossible to secure acreage the gravel is paid for at so much per cubic yard as measured in the trucks delivered on the road. Contracts are let on competitive bidding at a unit price for loading, screening and hauling to the first mile point and a unit price per yard-mile for additional haul beyond the mile point. There is also a unit price bid for shaping and compacting at so much per hour for men and teams but generally this work is turned over to the state maintenance forces. While most gravel hauling is done in the Summer it has been found that a considerable saving can be effected by doing this hauling after the ground is frozen, especially when long hauls are involved, for that enables the contractor to use heavy truck equipment at a greatly reduced price per yard-mile. When such hauling is done in the Summer it is required that pneumatic tire equipment be used in order to protect the subgrade from damage caused by heavy trucks with solid tires.

Stating that 25 per cent of the land in Louisiana was undrained, J. M. Fournery, state highway engineer, indicated the problem which confronted the state in the large mileage of swamp road to be planned and now under construction. Generally the swamp land was wooded and consisted of a top-soil of vegetable character overlying clay at various depths. The top-soil was generally only about 12 per cent solids. Construction consisted in clearing and then removing the top-soil. Then dredges dug a borrow canal parallel to the road fill and built an embankment of the clay subsoil.

Reviews the Coal Commission's General Recommendations

IN SUMMARIZING the recommendations of the United States Coal Commission Edward Eyre Hunt, speaking before the American Academy of Political and Social Science in Philadelphia, brought out the following points:

(1) The commission recommends that the government continue its fact finding and publicity work in both the bituminous and the anthracite coal industry and that the government regulate the industry through the use of its power over interstate commerce. (2) That an administrative agency through which these powers can be exercised be created as a coal division in the Interstate Commerce Commission. (3) Federal licensing of those who buy and ship coal in interstate commerce. (4) A federal tax on royalties and differential profits. (5) The adoption of a uniform standard of either the long or short ton. (6) A re-examination by the Interstate Commerce Commission of the differential railway rates with a view to the promotion of coal movement by water and the discouragement of long haul by rail. (7) A modification of the rules governing distribution of railroad cars in periods of shortage so as to give consideration to the ability of the producer to sell coal rather than to mere ability to produce and load it into cars. (8) That contract coal be given preference over spot coal delivery. (9) That the government as administrator of 50,000,000 acres of coal lands amend the leasing laws so as to restrict the opening of new bituminous mines. (10) That Congress designate an agency to unite with the industry in studies of unemployment and the wage structure, which agency will serve as a medium of publicity for rate information and will be prepared to make special compulsory investigations whenever there is a threat of

failure to renew a wage agreement. (11) Continuous publicity as to labor relations with the possible resort to mediation at the instance of the President of the United States. (12) The commission does not recommend nationalization of the mines, compulsory arbitration, compulsory incorporation of the unions, nor price fixing by the government. (13) The commission recommends the consolidation, grouping or pooling of bituminous mining operations, under such restrictions as are prescribed for railroads in the Transportation Act. (14) That state and federal governments co-operate in inspection, revision of mining codes, supervision of compensation insurance, and safety education. (15) That communities license retail coal dealers, organize co-operative associations, open municipal fuel yards or in other ways deal with the problems of local distribution of coal.

The commission recommends to the industry (16) a number of improvements in management methods and the development of efficient mechanical devices to improve the general mining operations. (17) Attention is drawn to the British wage plan which provides that miners and operators share the profits of the business. (18) Better living conditions for the miners. (19) Co-operation with the miners in the study of unemployment and the rate structure, and in setting up boards of conciliation and voluntary arbitration. (20) Improvements in personnel management, training of foremen, and centralized responsibility in labor relations. The commission also recommends the appointment of district and national labor commissions to work out a national labor policy. (21) Collective bargaining to work out a system of national negotiation with district agreement is recommended. (22) The check-off and complete unionization are not recommended.

To the individual coal consumer the commission recommends (23) the buying for regular delivery on contracts and the storing of coal, as well as wider use of technical information regarding methods of fuel economy. (24) Wider use of substitutes for anthracite.

Revaluing Power Properties from Old Records

Under a decision rendered Oct. 27 by Chief Justice McCoy, the District of Columbia Supreme Court is to revalue the properties of the Potomac Electric Power Co., using as a basis the valuation data gathered in 1916-17 by the Public Utilities Commission. The litigation has been before the courts several years, and meanwhile a fund which now exceeds \$4,000,000 has accumulated through impounding of the difference between the rate for electric current collected—10 cents—and the rate fixed by the commission, varying from 8 cents to nearly 9 cents. The Public Utilities Commission fixed a valuation on the company's properties for rate-making purposes and announced its decision in 1918, reducing the rates, whereupon the company appealed to the courts, alleging that replacement values had not been allowed by the commission on existing prices, and also that some items had been excluded erroneously. The District Supreme Court denied the injunction; the District Court of Appeals reversed this, and the United States Supreme Court refused jurisdiction last spring, thus allowing the reversal of the Court of Appeals to stand. The company then contended that the entire valuation work must be done over, while the commission contended that the District Supreme Court had the authority to make a revaluation from the old records.

Hints That Cut Cost and Time For the Contractor and the Engineer

Filtered Sprinkling Water Used To Avoid Iron Stains in Concrete

BY G. C. HABERMEYER
Engineer, Illinois State Water Survey

CONCRETE placed in the University of Illinois stadium was to be kept wet for 21 days before forms were removed. Water applied to the lower tiers of seats by sprinkling continuously, using a common type of lawn sprinkler, caused an objectionable stain where the water flowed along one course for any considerable time, due to an iron content of 2 p.p.m. in the water. To improve the appearance of the structure a

STADIUM STAINED BY IRON IN SPRINKLING WATER
No stains show between portals where water used was filtered and applied evenly by hand.

pressure filter was installed to remove the iron. The pressure available to wash the filter was not adequate and at times an appreciable amount of iron was left in the water. Further improvement was effected by sprinkling parts of the structure by hand thus securing a more uniform distribution. During the latter part of the work, the seats were covered with sawdust or sand which reduced the amount of water needed.

The view shows stained seats below the portals, which were placed before the filter was installed, and seats between the portals with comparatively little stain which were placed after the filter was installed.

W. A. Slater is in charge of the concrete work for the athletic association of the university and the State Water Survey assisted in plans and installation of apparatus used to reduce the iron stain.

Count of Football Crowds Gives Hints on Stadium Design

BY CLYDE T. MORRIS
Professor of Structural Engineering, Ohio State University,
Columbus, Ohio

WHILE preparing plans for the stadium at Ohio State University, the writer was impressed with the lack of information as to the number of people which could be accommodated through entrances of various dimensions, on ramps, and on stairways. During the past football season some data have been gathered on this subject at the Ohio stadium which may be of interest.

The design and construction of the stadium was described in *Engineering News-Record*, Oct. 19, 1922, p. 640. The seating capacity is approximately 62,000. There are 39 arch openings on each side of the stadium, provided with iron gates, and turnstiles for taking tickets may be placed at as many of these as necessary. This year 23 turnstiles were used. After the game, all gates are opened, which leaves the sides practically unobstructed for the crowd to pass out.

After the tickets are taken at the turnstiles, the crowd finds its way to the seats by means of 12 portals on each side to the 4 ft. 6-in. level near the bottom of the seat bank through which the lower 32 rows are fed, and six ramps which feed the upper 14 rows of the lower deck and the 22 rows of the upper deck.

At the dedication game, Oct. 21, 1922, there were 70,000 people packed into the stadium, but due to the newness of the structure and the inexperience of both ushers and ticket takers an exact count of the various entrances is not available.

During the season just closed the turnstile counts at the five home games were: Wesleyan, 25,294; Colgate, 27,819; Dennison, 17,247; Iowa, 40,202, and Illinois, 36,877.

The gates were opened at 12:30 p.m. and the games called at 2. The maximum number of people handled through one turnstile was 3,069 and the average of the four next highest was 2,575. A count of persons passed through a single turnstile for 10 successive minutes averaged 46 per minute. There were two men at each turnstile, one taking tickets and the other operating the turnstile. At the student gate, where the tickets had to be torn from books, the best average for 10 successive minutes was 25 per minute.

Observations during the passing of crowds revealed the following facts:

Portals—There is no congestion of people at any point preceding the game except before the turnstiles, and at these the lines are seldom long. Due to this fact no data are available as to the number of people who could enter the seat banks by the various portals and ramps. The crowds always flowed through these freely. The count showed that averages of 20 and 21 persons per minute passed up a flight of eight steps and through a portal 6 ft. wide. At an average pace

of 90 steps per minute and people two steps apart and three abreast, these openings would accommodate 135 persons per minute.

Ramps—The ramps which feed the upper part of the lower deck and the upper deck have short flights of steps at the bottom and top which limit their capacity. The stairs are 9 ft. 3 in. wide and the ramps are 8 ft. 2 in. wide with a slope of about 15 per cent. These ramps accommodate an average of from 50 to 55 persons per minute while the capacity, figured on the same basis as the portals above, and counting five persons abreast, would be 225 persons per minute.

Exits—After the game the exits from the seat banks would be crowded for a period of from three to five minutes. Various exits showed the following actual count of persons passing out: Lower portals, from 100 to 112 persons per minute as compared with the theoretical 133 given above; and ramps 210, 240 and 190 persons per minute during six minutes of count, as compared with the theoretical capacity of 225 given above. The capacity of these ramps is limited by the stairs at the top and bottom.

This Is Not a May-Pole Dance

PICTURED above are Chinese coolies tamping an earthen dike thrown up as part of a flood-protection development carried out to keep the Yellow River, China, under control. Work was done by the Asia Development Co. Your guess as to what the device is made of is as good as ours.

Conveyor on Sewer Job Saves Labor of Four Men

DIVERSITY of use to which elevating equipment may be put is not usually fully understood by many contractors who may rely too greatly upon manual methods where economy would seem to demand installation of machinery for materials handling. A good example of the economy of mechanical means is to be found on a Milwaukee sewerage job, Wenzel & Hennoch being the contractors.

For concreting below ground, two surface plants have been arranged, the conveyor and bin system having been decided upon after two other methods had been tried. A bucket elevator was discarded because it was not fast enough, and the use of a dump car running to the mixed skip from storage piles in the street, used too many men. From a gang of seven by this latter method installation of a belt conveyor reduced the number to three. One man only is required at the conveyor and he is available half the time for other work. At 60 cents an hour per man the monthly saving

From Job and Office

Hints that Cut Cost and Time

in labor by the installation of the conveyor amounts to around \$500. It is therefore easy to see that the equipment would soon pay for itself through the economies that it effects. Then when the job is finished the conveyor will have been paid for and can either be used on other work, or turned in for resale with profit to the contractor.

The bin shown in the accompanying view holds 30 cu.yd. of stone and 15 yd. of sand. From this bin the

BELT CONVEYOR USED ON MILWAUKEE SEWER JOB

material is proportioned for a mixer below. The conveyor loads the bins in the morning, being shifted so as to discharge into either the sand or stone compartments. It has unloaded ten large trucks of 4-yd. capacity in 50 minutes. The regular hopper has been built up on each side, the width of the track. A wooden ramp enables the truck to get to the proper dumping height above the hopper.

The information contained in this article was secured from the Barber Greene Co., East Aurora, Ill.

14-Story Reinforced-Concrete Hotel Built in Winter Months

EXTENT to which cold weather concreting may be carried if adequate protective measures are provided is illustrated in the construction of the Keenan Hotel in Minneapolis during the winter of 1922-23. The contract for the building was not let until late in the fall and excavation did not start until Dec. 1, 1922. The ground floor of the building was concreted on Dec. 26, 1922, and the last floor of the 14-story structure on March 2, 1923. This means that all stories were concreted in three months' time—an average of more than a floor per week.

Instead of materials being exposed to cold weather and then heated just before use, they were kept in an inclosed building at the rear of the one under construction. This materials building was kept at the same temperature as that in the portions of the building under construction, or 50 deg. F. As concreting materials were needed, they were conveyed in proper amounts from the storage room and dumped into the mixer, which was placed in a pit below the first floor. Concrete was then hoisted to a level about 20 ft. above the floor being concreted and then chuted into the forms.

Heating was accomplished by salamanders which

From Job and Office

For Contractor and Engineer

FIVE FLOORS PROTECTED DURING WINTER CONCRETING OF HOTEL

Canvas was fastened at the top and bottom of each floor so that only one floor had to be uncovered at a time. Thus, protection was offered each floor from four to five weeks before being exposed to the cold weather.

burned coke. One salamander was assigned to 750 sq.ft. of space, or 6,750 cu.ft. From fifty to sixty salamanders were in use during construction.

Owing to the fact that concreting was carried on so rapidly, five floors were covered at a time. The canvas used was of a heavy quality. It was so placed that it could be removed from any one floor independently of the rest of the floors. Inasmuch as five floors were thus offered protection, the newly placed concrete in any given floor was kept under cover for a period of four to five weeks. Since the temperature was maintained at 50 deg. or higher, the concrete had ample opportunity to cure before it was exposed to cold weather.

The record time for concreting one floor was three and one-half days and most of this time was taken up in the building of forms, placing of steel, etc. The actual time for placing the concrete in one floor (approximately 200 cu.yd.) was 7½ hours.

The hotel was built by the Fleisher Construction Co., Builders Exchange, Minneapolis, Minn. Cost of the completed structure was in the neighborhood of \$1,000,000.

Reinforced-Concrete Piles Fitted With Shoes and Sails

By HARRY J. FINEBAUM

Resident Engineer for Clarence W. Hudson, Hill-to-Hill Bridge, Bethlehem, Pa.

ONE OF the piers of the Hill-to-Hill bridge at Bethlehem, Pa., situated between the tracks of the Lehigh Valley R.R., was founded on reinforced-concrete piles. One hundred piles were successfully driven to rock or refusal, through an overlying bed of sand, gravel and boulders. Twenty-five piles were 25 ft. long while the other 75 were 32 ft. long, these lengths being determined by three reinforced-concrete test piles previously driven. The piles were not all driven their full length,

because of the hard driving encountered, but the driving was materially aided by two special features: a cast-iron shoe integrally built with the pile; and an internal jetting pipe with twin outlets also integrally built into the pile.

The shoe is shown in Fig. 1. The part in contact with the concrete was of the same shape and cross-section as the point of the pile, and from there on it tapered down to a 2-in. tip. The areas of the tip of the shoe and the foot of the pile proper thus bore a close relationship to their respective crushing strengths. In order to hold the shoe securely in the concrete of the pile, four holes about 2 in. deep were tapped and threaded in the head of the shoe. Into these holes were screwed four ½-in. diameter steel bolts about 2 ft. 6 in. long. After the rods were inserted in the shoe, they were bent so that they all crossed each other as shown.

Pouring Concrete from Dump Buckets

DEFORMATION of formwork is liable to result if care is not exercised in dumping concrete when it is placed by dump buckets. To obviate form distortion J. D. Miller, carpenter foreman on Anderson & Bros.' contract at the Tipton dam, Pennsylvania, devised the method herein illustrated of controlling flow of concrete from bottom-dump buckets. The device is merely a light rope with a hook fastened on one end. The hook is placed over the top edge of the bucket and the rope is passed under the bucket and two turns of it are taken around the bail. The doors can then be held to the desired opening.

The whole thing was set at the end of the pile form thus acting as an end form when the pile was cast.

The jetting pipe is shown in Fig. 2. It consisted of three parts: the twin outlet, the tube and the elbow-nipple inlet. To cheapen the cost of these pipes, the twin outlet and the tube were made of light-gage galvanized sheet metal with soldered longitudinal and transverse joints, while the inlet was made up of standard 1½-in. iron pipe fittings.

The jetting pipe was held in the center of the form by wiring it to the radial ties of the reinforcing system in the piles.

FIG. 1—DETAILS OF SHOE FOR CONCRETE PILE

FIG. 2—JET PIPE AIDS IN PILE PENETRATION

The two ends of the twin outlet were reduced to $\frac{1}{2}$ -in. diameter so as to produce a high nozzle pressure, and were located immediately above the head of the pile. These ends were cut to be parallel to the sides of the pile form.

When they did not snugly fit against the sides of the form small wooden plugs, $\frac{3}{4}$ in. square, were inserted between them and the form so as to form a seal against the entering of mortar into the pipe. These plugs were removed after the forms were stripped from the concrete piles.

Before driving the piles, a steam hose was attached to the nipple of the jet inlet and live steam forced through the jetting pipe, to insure a clear passage.

Spherical Steel Tank Is Novel Structure

SPHERICAL tanks represent a new development in tank design in order to meet the requirements for storing oil products of high volatility. The first of several such tanks, designed and built for the Texas Co. at Tulsa, Okla., by the Chicago Bridge & Iron Works, is shown in the accompanying views. It is

From Job and Office

Hints that Cut Cost and Time

into vapor, much of which is lost when the tanks are opened or when the pumps are started to remove the liquid from the tank. If sufficient pressure is maintained inside of the tank, the casing-head gasoline will be maintained as a more or less stable liquid.

Until about two years ago refined oil products of this kind were stored under pressure in small cylindrical tanks, but as the manufacture increased, attempts were made to store them in larger tanks. The oil men naturally turned to the flat-bottomed storage tank commonly used for the storage of oil and ordinary gasoline, but found that this type did not lend itself to pressure storage. It was evident that the expense of building foundations and anchoring a flat-bottomed tank thereto would practically prohibit the use of this type of tank. As a first step, therefore, H. B. Murphy, manager of the Dallas office of the builders, adapted the design of an elliptical-bottom elevated steel tank to withstand pressure by adding a roof with the same shape as the bottom and designing it for a working pressure of 15 to 20 lb. per square inch. The first tank of this nature, of 10,000 bbl. capacity, was built for the Phillips Petroleum Co. at Bartlesville, Okla. While it was found successful in operation there was doubt as to whether the design was the most economical.

That a spherical tank would make a better design to meet the conditions was suggested by George T. Horton, president of the Chicago Bridge & Iron Works, and the

BUILDING A SPHERICAL TANK FOR VOLATILE OIL PRODUCTS

18 ft. in diameter, with a capacity of 10,000 bbl. or 120,000 gal.

In the storage of casing-head gasoline and other highly volatile refined products of crude oil it is necessary to keep them under pressure. Otherwise such products will boil at ordinary temperatures and pass

original design was changed to fit this idea. The "hortonsphere," as this spherical tank has been named, is said to have proved a complete success. As far as the detailing of the "hortonsphere" is concerned, it is very similar to the standard practice developed by the company in the construction of elevated steel tanks.

For Contractor and Engineer

Job and Office Notes

In Connection With an Abstract of the Report on "Renewing Railroad Culverts" heard at the recent convention of the American Bridge and Building Association, and printed in these columns recently, Leonard M. Sandston, consulting engineer of Middletown, Ohio, and associated with the Armo Culvert & Flume Manufacturers Association recalls renewals which have been made by the use of corrugated culvert pipe. "P. F. Jones, reported in *Engineering News-Record*, Aug. 24, 1922, p. 321," writes Mr. Sandston, "how he solved the problem of carrying the south branch of the Davis-O'Connor drain under the main line of the Southern Pacific R.R., and underneath a paved highway without any interruption to traffic by using an Armo corrugated culvert pipe as a tunnel shield to bore through the embankment, with an ordinary screwjack supplying the motive power. The pipe, although unprotected on the driving end, was quite uninjured at the end of the job. Other instances of this kind have been reported from time to time, as follows: R. V. Merkle, engineer to the Turlock Irrigation District, Stanislaus County, Calif., successfully jacked a 36-in. diameter corrugated culvert pipe through a fill of stones and hardpan, under a concrete paved road without any damage either to road or pipe. At Ingalt, Ill., in 1911, 120 ft. of 48-in. diameter corrugated culvert pipe was jacked under the main tracks of the Chicago Great Western R.R. through a fill 35 ft. high. Where it is at all possible to use this method, especially on railroad work, it would appear to have a distinct advantage in that no interruption of traffic is entailed."

When the *Compania Hidroelectrica a Irrigadora del Chapala*, S. A., of Guadalajara, Mexico, installed their new Las Juntas power house they were confronted with a difficult problem in getting heavy equipment to the site of the power house. There was no railroad reaching the site of this plant and, moreover, a typical Mexican mountain intervened between the nearest railroad and the power site. The solution of this problem was the installation of a wire rope incline 4,370 ft. in length. The total difference in elevation between top and bottom of this incline is 1,722 ft., and the greatest degree of inclination is 39 degrees. It is equipped with a Lidgerwood hoist having a 105-hp. G. E. motor. The car is lowered by a 12-in. patent flattened strand Hercules (red-strand) haulage wire rope. Loads weighing up to 15 tons are handled. This incline was installed in about the middle of 1922 and is still in use. Eight round trips is the average daily mileage of the car.

Building a Reinforced-Concrete Structure without form-work may sound like a peculiar process, but it has been done by a farmer in the construction of a small storage cellar, says a recent issue of the house organ published by the Alpha Portland Cement Co. The spot designated as the location for the cellar was marked on the ground by means of chalk lines accurately squared. The area so marked represented the lines formed by the inner wall and was 8 ft. wide and 12 ft. long. The center of the space was crowned with clay, the center being raised about 12 in. or more from the side. After this crown had been placed it was tamped thoroughly with a wooden mallet and finally smoothed off. Trenches were then dug for the four walls. Care was taken during the digging to see that the inner wall of earth was kept as near true and unblemished as possible. The trench was made wide enough at the top for the digger to work in easily. Walls were 8 ft. high. Before any concrete was poured a door frame 3 ft. 4 in. was made of 8-in. boards and

braced. This was then set against one end of the cube of earth, centered and made secure. Concrete was then dumped in about the bottom of the trench until about a foot high whereupon 1-in. boards were placed on the outside of the concrete and earth shoveled on the outside of the board. As soon as the concrete reached the top of the board, the board was raised and loose earth fell against the wet concrete wall, keeping it from spreading. In this way the four walls were built up. Reinforcing was used in short lengths at the corners. When all the concrete was in and had properly set the interior of the cellar was excavated. Hand shoveling and a team with a slip scraper accomplished the excavation. Interiors of walls were found to be almost as smooth as though wooden forms had been used. This method is prescribed as being satisfactory only in walls of unusual compactness—in other words, either heavy clay or soils.

In Connection With the Installation of a new pumping outfit at Tully, New York, recently, it was found necessary to cut a section about 8 by 12 in. through the side of a steel basin $\frac{1}{2}$ in. thick in order to admit the suction pipes, writes Louis Mitchell, dean of the L. C. Smith College of Applied Science, of Syracuse University. The top of the steel casing was flush with the ground so a trench was opened about 6 ft. deep at the point where the pipes were to enter. In order to obviate delay in cutting the opening with a drill or torch (the latter not being available in the village), the plant attendant who is an expert rifleman brought out his rifle and shot holes around the section to be removed. These holes were made from $\frac{1}{2}$ to $\frac{3}{4}$ in. apart and the section was then chiseled out, taking only a couple of hours to complete the work. A No. 303 "Featherweight" Savage rifle was used with soft nose bullets. The attendant stood about 20 ft. away from the tank and as the trench was darkened by the building over the basin, a lantern was set by the side to light the section exposed. The shots were fired at an angle so that after piercing the steel shell they entered the water and did not damage the other side of the tank.

An Application of the Welding Process which illustrates the value of oxy-acetylene welding in the fabrication of steel structures as well as the possibilities offered for reclaiming used material has recently been demonstrated by a midwestern concern which has designed and built a well drilling driver constructed of reclaimed pipe and fabricated by welding and cutting. This driver has been used to drill a number of artesian wells, and has very satisfactorily stood up under the severe usage to which it has been subjected—according to the Linde Air Products Co. The drilling driver is built of 2-in. pipe and other material reclaimed from the scrap pile. It consists of two uprights 25 ft. high with a cross-bar 5 ft. long, all of 2-in. pipe; these forming a rectangular structure open at the bottom. The crossbar is joined to the uprights at the two corners by welding. The uprights rest upon two base plates 12 in. square and $\frac{3}{4}$ in. thick, and are welded to these plates. The frame is braced by welding two pieces of 2-in. pipe from the crossbar to the two uprights. Eye-bolts are welded to the top and about the middle of the frame on each side and guy wires are attached to these. When the driller is in use the guy wires run from these eye-bolts to iron stakes 15 in. long and $\frac{3}{4}$ in. in diameter which are driven into the ground. A collar welded to each of these stakes prevents the guy wire from slipping off. The hammer is made of a section of 14-in. pipe to the bottom of which a round piece of 1-in. plate has been welded. The hammer is weighted to give it a total weight of about 150 lb. and a piece of 2-in. plate is welded to the top. An eye-bolt is attached to the center of the top plate by welding, this being the point of connection for the cable by which the hammer is raised. The cable runs through a pulley which hangs from an eye-bolt welded to the top cross member and from this pulley the cable runs to the cable winding drum. Extending laterally from the hammer and welded to it are two arms. These are in turn welded to sleeves which slide up and down on the uprights and serve as guides for the hammer.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Help for a Federal Contract Law

Sir—I read with interest the editorials in *Engineering News-Record*, Nov. 1, pp. 203 and 205, one entitled "Function of Contracting" and the other, "For a Federal Contract Law." Both the subjects covered by these well-considered articles are pending before the Inter-Departmental Board of Contracts and Adjustments of the United States.

In the latter article, the sentence which especially attracted my attention was: "If the board follows its procedure in drafting the standard contract form to invite aid in arriving at decisions from the whole construction industry, engineers and contractors can play a useful part in formulating the general federal contract law. There are few employers of which they have more loudly complained in the past. Let them be as ready to help put away the causes of complaint."

The last sentence is good advice and I believe far more important than even you realize. I hope that you can see your way clear to make this exhortation stronger and clearer, and to accomplish this you may have to emphasize it by repetition. When I organized this board, I realized that contracts had to be fair and equitable to both parties. It was true that in the past high-class contractors and men who sold supplies to the government had in many cases just cause for complaint against the contractual procedure of the United States Government, including its form of contracts. In performing the task assigned of simplifying and standardizing as far as possible contract procedure and contract forms, I knew our work would not be of benefit unless we considered both parties to the contract. Not knowing or being able to know the other man's viewpoint without consulting him before the contract was drafted, I adopted the policy of inviting suggestions and constructive criticism of contractors, engineers, architects and others who might be directly or indirectly interested in government contracts. (All taxpayers are indirectly interested in this subject as in the long run they have to pay the cost.) Accordingly, I sent out several hundred copies of a tentative form of contract, accompanied by a questionnaire, and I can assure you that our board has carefully considered every constructive criticism which it has received. Some changes we would like to make are prevented by federal statutes which have been passed from time to time, not by the contracting officers of the United States Government, but by the congress elected by our citizens. Many of these statutes are unduly restrictive in the interest of the government against the contractor, and there are other objections well set out in your articles.

The subject of the new federal contract law, while important, is not a sensational subject to attract attention or throw the spotlight on any politician who might wish to advocate it or oppose it. Therefore, it is most important that thoughtful people, organizations and publications should continue the advocacy for such a law and show their congressmen and senators the necessity for the enactment of a non-political, non-partisan bill in the interest of the government and its citizens, whether they contract with it directly or not. I can assure you that the principle of consulting the other party in advance is being followed in relation to the new federal contract law, as I have written many letters asking for suggestions regarding this law, and I will appreciate any suggestions I can get from you as to how this matter can be brought forcibly before the largest number of your readers.

I also hope that you can further assist by having other suggestions sent in regarding the new standard form of contract which is now being considered by the board. Again

quoting you, "Let them be as ready to help to put away the cause of the complaint" by taking a little time to send in some constructive criticism.

GORDON A. RAMSEY,
Chairman, Inter-Departmental Board of Contracts
and Adjustments of the United States.

Chicago, Ill., Nov. 14, 1923.

Aluminum Paints Reduce Radiation

Sir—Reference is made to the article in *Engineering News-Record*, Sept. 27, 1923, p. 522, entitled "Radiation Reduced by Aluminum Paints." While the radiation from a surface bronze painted is greatly reduced, the transmission of heat by convection is not correspondingly reduced. In total, an aluminum or "gold" bronze coated radiator will give off about 76 to 83 per cent as much heat as an unpainted radiator of the same size and shape, with other conditions equal (cf., Bureau of Standards *Technical News Bulletin* No. 77 of Sept. 15, 1923, Art. 18). Radiators coated with ordinary oil paints and enamels give off from 97 to 103 per cent as much heat as an uncoated radiator.

New York, N. Y.,

Oct. 26, 1923.

G. S. BURRELL,

Commander, (CEC), U. S. N.

Vibration in Water Wheels

Sir—It is possible that another contributing cause to the troublesome vibrations in the runners of hydraulic turbines, mentioned on p. 764 of your issue of Nov. 8, 1923, is that the frequency of the fundamental note of the individual vanes of the runner agrees with or is a simple multiple of the frequency of the pressure changes. A number of years ago I found that this was the case with the rotor of a steam turbine, the plucked tone of a single (small) blade having a frequency almost identical with that given by the r.p.m. of the rotor. The substitution of thicker blades, having a lower fundamental, did away with the steady breaking of blades that had nearly prevented the sale of the product.

In the case of the runner that produced the record given in Fig. 3, p. 764, there were about 150 vibrations per second, or a vibration each time a runner vane, at 450 r.p.m., passed each one of the twenty guide vanes. The fundamental note would be not far from D in the bass clef, not unreasonable for a piece of metal of the size indicated. The cutting away of the strips on the edges of the vanes would not only muffle the pressure changes and decrease the efficiency by increasing the thickness of the water ring, but the change would also increase the frequency of the fundamental note of the runner vane and so prevent it from synchronizing with the pressure changes.

H. S. S. SMITH,

Stroudsburg, Pa.,

Nov. 14, 1923

Emeritus Professor of Civil
Engineering, Princeton University.

Publicity for Proposed Laws

Sir—Regarding your editorial in the Nov. 15 issue of *Engineering News-Record*, p. 788, entitled "Power and the People," which referred to our recent election and the proposed constitutional amendment covering water power development on state lands in the Adirondacks, you do not mention the cause, which, in my opinion, had more to do with the defeat of this measure than any other. That is the practice of the majority of the voters in voting No on general principles on all propositions which they do not understand. I know that was the case in this city, where the people do not take a great deal of interest in the public parks in the Adirondacks. Questions like this are decided largely according to whether the proponents or opponents put forth the better grade of propaganda. There was so little agitation on this question previous to election that it is not surprising the amendment was lost.

Let those who are materially interested in having such an amendment pass do a little advertising and educate the voters regarding the wisdom of passing the measure, and possibly it will have better success next time.

Jamestown, N. Y.,

Nov. 17, 1923.

WALTER F. SHAW,
Consulting Engineer.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

All Missouri Road Construction Records for the State Highway Commission were broken during November when \$1,907,461.94 was actually paid to contractors for completed work.

Voters of Aberdeen, Wash., on Dec. 1 passed Wynoochee power project bill involving the expenditure of \$2,000,000 to provide additional water supply and hydro-electric power for the city. The mayor and city council are pledged to secure complete cost data before proceeding with actual work.

At the Annual Convention of the American Society of Mechanical Engineers held in New York City last week, John R. Freeman, past-president of the American Society of Civil Engineers, was awarded the A. S. M. E. medal. The award was made for his service to industry through his activities in fire prevention.

The Temple Bill, Providing for the completion of mapping the United States in twenty-five years, will have the endorsement of Secretary of War Weeks and Secretary of Interior Work, assurances to that effect having been given recently by these officials to L. W. Wallace, executive secretary of the Federated American Engineering Societies, who explained the need of this legislation to the two secretaries.

City Planning and Zoning at Nashville, Tenn., has been made the subject of study of the Engineering Association of Nashville, which recently submitted a brief report on the subject to the city authorities. The local situation was reviewed and a number of recommendations made. A paragraph in the report of broad general interest is one advocating that the association assist "the city engineer in bringing the public and the city government to a due appreciation of adequate municipal engineering practice and work." A. F. Ganter is chairman of the committee named.

To President Coolidge Has Been Addressed a letter by Dean Hugh Miller of George Washington University protesting against the removal by Secretary of Interior Work of A. P. Davis, former director of the U. S. Reclamation Service and an alumnus of the Coreoran Scientific School, predecessor of the George Washington University Engineering School, the protest being made "because Dr. Work's action is so detrimental to the technical work of all departments of the government." The letter requests the President to take official cognizance of the matter and to have a thorough examination made of all the events leading up to this action of the Secretary of the Interior.

State Highway Officials Hold Annual Convention

Constitution Revised—Organization Plan Laid Before Members—
Department Turnover and Legislation Leading Topics

Engineering News-Record Staff Report

With representation from all but two states among the 200-odd state officials present, the American Association of State Highway Officials carried through an extensive program of technical discussions and committee work in the four-day meeting at New Orleans, La., Dec. 3-6. Development of committee work was the prominent feature of the meeting. With the exception of the annual message of Thomas H. MacDonald, chief of the Bureau of Public Roads, one full day was devoted to ses-

sions of the 12 committees and sub-committees, and a large part of two sessions was occupied in considering the reports of these committees. It was clearly indicated that, as the committees developed their plans and as research studies now well begun are completed, the technical activities in annual convention will consist largely in the reading and discussion of committee reports.

CONSTITUTION REVISED

Three classes of members, active, associate and honorary, with dues of \$10 for active and \$6 for associate members, or dues of \$200 for an entire state department, were agreed upon. Only active members can vote and they must be chief directing officials of state road departments. The associate member classification provides for subordinate officials. Honorary membership provides a place for "former state and territorial highway officials and the professors of highway, engineering in accredited universities," and for others who "shall be proposed by a member and elected by the executive committee." It is provided further that in case the president, who must be an active member, shall retire from official connection with state highway administration or shall leave the office vacant by other reason, the vice-president shall act as president in the interim between annual elections.

In the new organization, a president and executive committee act through bureaus of administration, special assignments, general office, publications and standards and through such committees and sub-committees as may be necessary.

COMMITTEE WORK

Few of the committees have proceeded far enough to do much more than report progress. Publication will soon be made of the report on methods of conducting tests and of standards for metal bridges and culverts. The association journal, *American Highways*, is being issued quarterly. At present the committee funds are too limited to permit of any extension of its publication work. Recent organization of a committee on administration has permitted it to get no further than to adopt a plan of operations. A definite report at the next annual meeting was forecast.

The most active progress has been made by the committee on standards working through its sub-committees on plans and surveys, on design, on specifications, on traffic control, and on bridges and structures. No changes in the Bureau of Public Roads standards for making surveys and plans were considered now necessary by the com-

Federal Budgetary Provisions for Engineering Services

Washington Correspondence

In line with the desire of the administration to cut federal expenses so that there can be a substantial decrease in the national debt in the coming fiscal year engineering services have been given few increased appropriations in the report of Director of the Budget.

The budget which just has been submitted to Congress provides \$130,000 to enable the Bureau of Standards to co-operate with government departments, engineers and manufacturers in the establishment of standards, methods of testing and inspection of instruments, equipment, tools, and electrical and mechanical devices used in the industries and by the government. This includes the practical specification for quality and performance of such devices and the formulation of methods of inspection, laboratory and service tests. This will permit of some expansion of this work. The amount appropriated for the current fiscal year was \$100,000.

For the investigation of standards of practice and methods of measurements of public utilities, such as gas, electric light, electric power, water, telephone, central station heating, and electric railway service, the budget carries \$105,000. This is an increase of \$10,000.

For technical investigations in co-operation with industries upon fundamental problems involved in industrial development, with a view to assisting in the permanent establishment of new American industries, the budget carries \$180,000. This is \$30,000 more than was made available for use during the current fiscal year.

Britain Given Turbine Contract

The Newfoundland Power & Pulp Co. has awarded the contract for the seven Francis type turbines of 14,000 hp. each, or 98,000 hp. total, to Armstrong-Whitworth & Co., Ltd., England. The company is building on the Humber River in Newfoundland.

mittee on plans and surveys. Announcement of progress was made by the committee on transport. The committee on specifications called attention to the standards for contract and bidding forms reported last year and urged their greater use and recommended substitution where desired of negotiable securities for guaranteed bonds.

Design and construction received more definite consideration than any of the other committee subjects. The committee on relations with contractors reported only moderate progress in advance of the general principles laid down last year. Special effort was made by the contractors' unit of the joint committee to obtain definite action for bonding reform but action was limited to decision to hold a further meeting, with the bonding companies represented, to seek an agreement on policy practice.

The committee on design recommended the limiting of vehicle loads to 800 lb. per inch-width of tire and to 19,000 lb. on one axle. It limited vehicle length including trailer to 65 ft., overall width to 9 ft., height to top of load 12 1/2 ft., minimum axle spacing 5 ft. and wheel gage to 54 in. The maximum rim of solid tires was limited to a thickness of 1 1/2 in. Subgrade testing was recommended and also the use of a sand layer in unstable soils. The usefulness of tile drainage was considered to be undetermined. In slab design the formulas reported by the Illinois Bureau of Highways for edge thickness,

$$T = \sqrt{\frac{3W}{S}}, \text{ and for center thickness,}$$

$$t = \frac{7T}{10}, \text{ were recommended. The re-}$$

port favored modulus of rupture tests instead of crushing tests and longitudinal tongue-and-groove joints with dowels.

Following the extensive report last year in construction organization and management the committee on construction advocated these practices in detail: (1) Separate contracts as grades, surfacing, structures; (2) developing the use of local materials; (3) payment of materials in stockpiles; (4) fills to stand one year before surfacing; (5) use of 1-in. maximum size gravel without rolling; (6) longitudinal joints in concrete paving; (7) care to avoid segregation in stockpiles; (8) proportioning concrete by weight; and (9) the use of calcium chloride for curing.

BUSINESS ACTION

Perhaps the most important business action was the discussion to promote actively in the present Congress a federal aid program calling for an appropriation of \$100,000,000 yearly from July 1, 1925 for three years, and in addition \$10,000,000 for forest roads, 70 per cent of which should go to routes forming links in the federal-aid system. In his report the executive secretary called for active aid in advancing this program before Congress. In reporting a practice in financing road work the executive secretary gave the following figures of the sources of income in percentages:

Source	Construction	Maintenance
Taxes	51.8	15.9
Appropriations	35.8	35.7
Grants	9.5	16.4
Other sources	2.9	2.0

Officers for the ensuing year were elected as follows: President, F. R. White, chief engineer, Iowa Highway

Sir William MacKenzie Succumbs

Sir William MacKenzie, Canadian railroad financier and builder, died in Toronto on Dec. 5 after a long illness.

He was born in Kirkfield, Ont., Oct. 30, 1849, was educated in the public schools and later attended the military school at Toronto. He taught school for a short time after leaving that institution and then went into business. When in the Toronto and

Nipissing line of the Grand Trunk was being built he went into railway contracting.

In 1886 he met Donald Mann and went into partnership with him, a partnership which resulted in the construction of the Canadian Northern Ry. as a transcontinental line, a work that brought knighthood to both men. Sir William MacKenzie served as president of the Canadian Northern Ontario Ry., and of both the Winnipeg and Toronto street railways and numerous other smaller public utilities.

A fuller biography of Sir William MacKenzie will be given next week.

Lord Shaughnessy Dies

Thomas George Shaughnessy, more familiarly known as Sir Thomas Shaughnessy, and recently as Lord Shaughnessy, chairman of the board of directors of the Canadian Pacific Ry., died suddenly of heart trouble at Montreal on Dec. 10, aged 70 years.

Lord Shaughnessy was born in Milwaukee, Wis., on Oct. 6, 1853. He attended the public schools of that city and when 16 years old entered the employ of the Chicago, Milwaukee and St. Paul Ry. In 1882 he went to Canada with Sir William Van Horne as general purchasing agent for the recently organized Canadian Pacific Ry. He continued in the service of that railway company during the remainder of his life, becoming assistant to the president in 1889, a vice-president and director in 1891, and president in 1899, retiring to become chairman of the board of directors in 1918. It was largely through his efforts that the Canadian Pacific became the great rail and water transportation system that it is today. His services to his adopted country were recognized by knighthood in 1901, by the rank of commander of the Victorian Order in 1907, and in 1916, for his distinguished services to the empire in the war he was elevated to the peerage.

Drainage Congress at St. Louis

The National Drainage Congress has selected St. Louis for the annual meeting, to be held Jan. 16 and 17. The Levee and Drainage Contractors Association will hold its meeting at the same time and place. C. S. Gannon, St. Louis, is secretary of both organizations.

Commission; vice-president, F. F. Rogers, state highway commissioner, Lansing, Mich.; secretary, C. M. Upham, state highway engineer, Raleigh, N. C.; and treasurer, F. T. Sheets, superintendent of highways, Springfield, Ill.

Harbors Congress Debates Chicago Water Diversion

Strong Argument Counters Opponents' Claim of Navigation Damage, Treaty Contravention, Etc.

Engineering News-Record Staff Report

A debate on the diversion of Great Lakes water through the Chicago drainage canal into the Mississippi River was a leading feature of the nineteenth National Rivers and Harbors Congress, held at Washington, Dec. 5-6. W. G. Bruce, of Milwaukee, and C. A. Maguire, mayor of Toronto, Ont., attacked the diversion, while G. S. Williams, Ann Arbor, and R. I. Randolph, Chicago, defended it. No decision was rendered.

Mr. Bruce raised the question whether one region shall be permitted to injure another and persistently defy the law and violate government orders. He stated that Great Lakes shipping suffers a yearly loss of \$750,000 per inch of decrease of navigation depth, or for the 6-in. decrease caused by the Chicago diversion a total of \$4,500,000 per year. He questioned whether compensating works such as have been proposed by the Chicago Sanitary District would effectively compensate, and held it doubtful whether Illinois could legally spend money on works in other states.

Mr. Maguire stressed the international phase of the question and criticized sharply the Chicago claim that it cannot dispose of its drainage without polluting waters that are a common possession. He asserted that Chicago is the only large city that continues to dispose of its sewage in raw state and he pointed as an example to the requirement placed upon Toronto by the government authorities of Canada that it purify its sewage and refrain from discharging it raw into Lake Ontario.

PROPOSERS OF DIVERSION

Gardner S. Williams denied categorically and in detail that the Sanitary District diversion of 10,000 sec.-ft. is contrary to law or to federal authority, that the primary purpose of the diversion is power development, that the diversion contravenes the 1909 treaty with Great Britain, and that the diversion damages navigation. Mr. Randolph reviewed a considerable number of arguments presented against the Chicago diversion. He showed that Chicago is now spending great sums of money for sewage purification, this, however, applying only to the sewage flow exceeding the diluting capacity of the 10,000-sec.-ft. drainage canal flow. He countered the charge that the lower rivers are polluted, by referring to the dismissal of the St. Louis suit and to the fact that all the river cities discharge raw sewage into the rivers. He answered the charge of navigation damage on the Great Lakes by describing the lake-level fluctuations due to other causes, and claimed that the magnitude of these fluctuations robbed the lowering due to the Chicago diversion of all real effects.

He also denied with detail argument the charge of violation of law and violation of treaty obligations, and stated on the question of violation of law that the case is still in court. He asserted that Canada is now drawing a large amount of water in excess of its treaty allowance, and charged that the violation is so flagrant as to lead the International Joint Commission to appoint commissioners to determine the amount.

Founder Societies Discuss Power Development

Mechanical Engineers, Closing Annual Convention. Meet with Civil and Electrical Societies

Engineering News-Record Staff Report

As a part of the program at its annual meeting the American Society of Mechanical Engineers held a joint meeting with the civil and electrical engineering societies to discuss the development of hydro-electric power. The meeting was held in the Engineering Societies Building, New York, Dec. 5 with Lewis B. Stillwell, past president of the A.I.E.E., presiding.

John R. Freeman, a consulting hydraulic engineer, and past president of both the civil and mechanical societies, opening the meeting with a paper on the principles underlying hydro-electric development, reviewed the improvements in the use of water power during the past fifty years and sketched some difficulties which have made many projects either poor paying or failures. Mr. Freeman foresees possible extensive changes in long-distance power transmission, making possible the economic development of isolated power sites, but he also feels that such improvements may have their present advantage largely offset by improvements in heat engines. Dissipation of the "propaganda and fog" which now surrounds the question of hydro-electric development and education of the public to understand that much of our power which now is "running to waste" cannot be developed, transmitted and distributed in our great centers of population at a cost necessary to compete with steam power, he believes. He takes the case of the St. Lawrence as typical, enumerating how some engineers claim that this power can be developed and sold in competition with steam power at great population centers, while other engineers are equally positive that it cannot be developed. In conclusion, Mr. Freeman said that our fundamental problem in the development of these resources is to determine how soon we need it, what it will cost, how much we can pay for it, and how much is needed.

OTHER SPEAKERS

John P. Hogan, a member of the civil engineering society and a consulting engineer in hydro-electric developments, gave an exposition of the pitfalls which face unwary designers of hydro-electric projects, summing up causes of such failure in the phrase "over-estimation of the amount of water and under-estimation of the cost." He stressed the fact that over-estimates of flow are due to our short-duration runoff records, none of which is long enough to give a true value for the minimum flow. Under-estimates of cost are due to the lack of complete preliminary studies of the power site, its accessibility, its surface features, and particularly its subsurface conditions.

Col. Hogan was followed by George A. Orrok, a member of both the mechanical and civil societies and a consulting engineer for the New York Edison Co. In his paper on water power costs vs. steam power costs, Mr. Orrok pointed out that the present low cost of coal, particularly in the great coast cities, and the high cost of transmitting hydro-electric power to these cities, gives steam power the advantage.

Subway to Replace Elevated Ry.

A proposition to replace the 6th Ave. Elevated Ry. in New York with a 4-track subway has been put forward by a large number of property owners along the avenue. The plan calls for five miles of subway to be paid for by a property assessment.

Reclamation Advisers Hear News-Record Editor

In his weekly news statement on the work of the Committee of Special Advisers on Reclamation, Governor Campbell, chairman, last week announced that the committee had taken testimony of F. E. Schmitt, associate editor of *Engineering News-Record*, concerning facts and views gathered on a two months' trip over a number of reclamation projects during September and October. Governor Campbell stated that Mr. Schmitt had contributed a large amount of valuable information and had apparently come to the conclusion that reclamation as a general policy is sound; that it would have rather violent ups and downs, but that it should be continued. Former Secretary Garfield expressed the opinion that much good would be done by the articles on reclamation published in *Engineering News-Record* in drawing greater attention to the problems of reclamation on the part of engineers.

Senator Gooding, who appeared before the commission during the week, laid chief blame for the troubles of the reclamation farmers at the door of the railroads. He advocated a five-year moratorium, reclassification of land and repayment on a forty-year plan.

Governor Campbell announced that the commission is gathering full information in regard to freight rates and other transportation matters.

According to his figures, hydro-electric power will not be able to compete successfully with steam power until the price of coal reaches \$10 or \$12 a ton.

The last paper of the evening was presented by Harold W. Buck, of the electrical engineers, on the interconnection of power systems. Its value lay in its clear statement that the major problem lies in the proper correlation of the two sources of power so that full advantage can be had of both systems of water and steam power. With diagrams Mr. Buck showed how, by the use of small blocks of steam power, the continuous output of a hydro-electric plant on a stream of variable flow could be largely increased. He mentioned the Cohoes plant on the Mohawk River as a typical example, wherein a steam reserve of 10 per cent made it possible to double the installation of hydraulic machinery. He does not think that a superpower system will reduce the general cost of power, but he does think that it will benefit manufacturing plants in isolated localities and will make it possible to develop water-power sites otherwise valueless.

The meeting was closed by some brief discussions and a general summing up by the chairman, in which he emphasized the necessity of standardizing the frequencies of our water and steam power plants so that a superpower system can be built up without excessive cost for changing machinery.

D.-O. Process Permitted for Austin, Minn.

However, State Board of Health Classes Plant as Chemical Treatment and Explains Position

Faced on the one hand with the conclusion that the electrolytic element of the direct oxidation process of sewage treatment adds materially to lime treatment alone except through the mixing of the paddles used in the electrolyzers and on the other by the opinion of the Attorney General that lack of proof of the efficiency of any portion of a proposed sewage-work is not sufficient to warrant disapproval of plans for the whole plant unless the questioned element is considered to be detrimental to the satisfactory working of the plans, the Minnesota State Board of Health has approved plans for the treatment of the sewage at Austin, Minn., by the direct-oxidation process, but as a chemical precipitation plant only, and with the distinct understanding that the "electrolyzers cannot be considered as more than devices for additional mixing of the line with the sewage until it can be demonstrated to the satisfaction of this board that the electrolytic portion of the process is of material value in the treatment of sewage."

The plans in question, at least in general outline, were submitted to the State Board of Health on Aug. 16. They included screens followed by lime treatment and the passage of the sewage through electrolyzers into settling tanks equipped with Dorr thickeners, the tank effluent to be discharged into the Cedar River. The sludge is to be pumped to a rotating filter then passed to a dryer. At a meeting of the board held on Nov. 6 a report was submitted to the board and action taken along the general line already stated, with the proviso that detailed plans and specifications should be submitted to the board in duplicate. On Nov. 16 the plans were submitted and approved.

CHEMICAL PRECIPITATION REVIEWED

The lengthy resolution adopted by the board on Nov. 6 includes in its preamble a review of the general status of chemical precipitation, in which it is pointed out that, aside from the very few direct-oxidation installations in use, the cities of Providence, R. I., and Worcester, Mass., are the only ones in this country where chemical precipitation is now in use, and that works which will permit the abandonment of chemical precipitation at Worcester are now being built. The preamble also expresses the opinion that while chemical precipitation in itself is satisfactory and produces an effluent that will be satisfactory, with ample dilution, so long as the "causticity due to the excess lime" continues, yet there is always the possibility of offensive decomposition when certain conditions arise. Should this happen at Austin it might be necessary to abandon a large part of the proposed plant, the preamble points out, since "caustic sewage cannot readily be treated" biologically.

It is understood that the City of Austin has not yet signed a contract for the proposed direct-oxidation plant but is to delay action until information can be had on the outcome of the tests of the process being made at Toronto under the direction of F. A. Dallyn, engineer, Ontario Board of Health.

Report on Rapid-Transit Lines for Detroit

Local Benefit Assessments Proposed to Pay for Most of System—
Alternative Plans

Reporting on rapid transit in Detroit, the city's rapid-transit commission (Daniel L. Turner, consulting engineer) has just advised the Mayor that the cost of a complete system will be so great as to make the solution of the financial problem the primary consideration, but that a complete system should be built, rather than individual lines as piecemeal items of a system, since the latter increase congestion and unbalanced city growth. The commission presents a plan for financing construction which would provide the larger amount of the required capital by local-benefit assessments, a smaller part by general taxation, and the capital for equipment by a bond issue. It indicates that either an underground system or a system largely elevated with short underground portions near the center of the city might be built, and states that a decision of which kind of system is to be built should be reached before a plan of routes is developed. The underground system would be more costly than the elevated but is otherwise preferable. The report does not in terms recommend either system. It says:

"The routes of the initial rapid-transit system for Detroit are dependent to some extent upon the type of structure. An underground system may be constructed along any street without injuring it. Elevated lines should be confined to the outlying sections of the city, but if such construction must be carried through the business centers the principal thoroughfares should be avoided and less important streets traversed."

UNDERGROUND SYSTEM

For the underground system, a new method of construction is recommended, called the "tunnelway" system. This would have its main portion constructed by tunneling, at sufficient depth to avoid service structures near the surface, but the stations would be placed at summits of the line and would be constructed by excavation direct from the surface. Such a system is estimated to cost \$3,200,000 per mile of double-track structure, and \$1,500,000 per mile for equipment, a total of \$1,700,000. The financial plan recommended would raise \$800,000, or one-fourth of the cost by general assessment on the city, and \$2,400,000, or three-fourths of the cost, by local assessment. The \$1,500,000 equipment cost would be met by mortgage bonds. An elevated system, with underground construction in the center of the city could be built for \$3,500,000 per mile, it is reported, \$2,000,000 of this amount being cost of structure. "Detroit can have a tunnelway system," the report states, "if it wants to pay the price. Otherwise it must accept an elevated system, with all the disadvantages that such a system means."

The present bonding power of the city is said to be not over \$30,000,000, and of this amount only a small part would be available for rapid transit construction. This is the basis for the financial plan proposed by the commission. Local benefit assessments, the report recommends, would be spread over the land a half-mile either side of lines.

Cleveland Names City Manager

At its meeting called especially for the purpose, city council-elect of Cleveland, Ohio, last week elected William Rowland Hopkins

as the city manager for that city. Mr. Hopkins will take office on Jan. 8 next. Meanwhile council will meet to fix the manager's salary, which is unofficially quoted as being near \$25,000 a year.

Mr. Hopkins, who is best known as an attorney interested in engineering development and municipal problems, is 54 years old. He was born in Johnstown, Pa., but went to Cleveland with his family as a child.

He is a graduate of Western Reserve University. His chief work for Cleveland has been in promoting the belt-line railroad.

Cornell to Hold Highway Conference

A conference on highway engineering is to be held at Ithaca by the Bureau of Highways of the New York State Department of Public Works, Dec. 18-20, under the auspices of the school of civil engineering of Cornell University. The program for the conference includes papers upon all phases of highway engineering and transport.

During the first day speakers will include Col. Frederick Stuart Greene, New York, H. E. Hiltz, Pennsylvania State Highway Department, Clifford Older, chief engineer of the Illinois Bureau of Highways; Harley C. Dunbar, assistant engineer of the New York State Bureau of Highways, and A. T. Goldbeck, of the Division of Tests of the U. S. Bureau of Public Roads. The first day's program will end with a smoker at which speakers will include Dean D. S. Kimball of the College of Engineering at Cornell, Dean W. A. Hammond of the University Faculty and Lowell Grossman, Commissioner of the Bureau of Highways in New York.

Traffic studies and regulation, and pavement maintenance will feature the second day's session. J. Gordon McKay, chief of the Division of Highway Economics and Transport, U. S. Bureau of Public Roads; John A. MacDonald, commissioner of highways, of Connecticut; Julius Adler, deputy engineer of the Bureau of Highways of Philadelphia; William A. Van Duzer, transport engineer of the Pennsylvania Highway Department; A. W. Brandt, second deputy of the New York State Bureau of Highways and Paul M. Tebbis, field engineer of the Pennsylvania Highway Department, will be the speakers.

The feature of the third day's session will be the conference of division and county engineers of the New York State Bureau of Highways. This conference is usually held at Albany. Previous to this conference, which will be held the afternoon of Dec. 20, "Essentials of Highway Construction" will be discussed by Theron M. Ripley, division engineer of the Bureau of Highways, New York; "Proper Relation Between Engineers and Contractors," by Roy Hall, division engineer of New York Highway Department, and "Snow Removal," by Frank F. Rogers, commissioner of highways of Michigan.

Explaining Osteopathy

Osteopathy is a new kind of therapeutics, separate from, and independent of the system of medicine. It covers in its comprehensive view the whole field of practice, including surgery and obstetrics, in which it has had signal success. It is more than manipulation. It is really adjustment. While the hands are used, it is not this alone and chiefly that constitutes its method of operation. *It is engineering, in the highest sense.* It is above the plane of "movements"—for there are no movements—no more than in bridge-building. The great principles of construction and production, the efficient action of multitudinous parts dependent on construction, the establishment of complicated processes in an interminable circle of causes and effects, all issuing in one united result—health—all these underlie the osteopathic idea of adjustable manipulation. — From "Osteopathy as Explained by The Encyclopedia Americana."

More Polar Determination

Sir—The instance of animal magnetism which you give in this column in your issue of Nov. 22 is very good. There is another instance, however, but no date is attached. Three Scotch sailors were caught in the fog off the coast and could not get their direction. Finally a piece of canvas was smoothed out, each man holding a corner. Then the national bird was produced from the bare breast of one patriot. It was flung onto the sail cloth, landing on its back, but it soon righted itself, crawled about in a circle and then struck off to port. Jock pointed in that direction and said: "Well, I'll no be for telling the north but there's the direct route to Scotland."

C. R. C.

ST. CLAIRESVILLE, OHIO, Oct. 26. —A deed sent here for recording the sale of a farm near Bridgeport gives the starting point for the surveyor's description of the acreage as a "mahogany tree." (PRESS CLIPPING.)

Private Capital to Develop Falls of the Ohio

Washington Correspondence

Following the recommendations of its engineers that private capital be allowed to develop the power in the Falls of the Ohio near Louisville in preference to having it developed by the city of Louisville (*Engineering News-Record*, Aug. 30, 1923, p. 362), the Federal Power Commission has issued a preliminary permit to the Louisville Hydro-Electric Co. covering this site. In line with this action, the commission has also denied the application of the City of Louisville for a preliminary permit covering proposed developments on the Cumberland and Green Rivers. The decision in the Falls of the Ohio case has been pending for a long period, while the commission considered the priorities which are allowed to municipalities under the water power act, and while it carried out an investigation as to whether municipalities are in a position to conduct the distribution and sale of power in areas outside of their jurisdiction.

The engineers in their report pointed out that in order to make this development effective, the municipality would have to construct a steam plant and distributing system as an auxiliary to it, which plant and distributing system the Louisville Hydro-Electric Co. already has available.

Last Section of Hetch Hetchy Tunnel Holed Through

The last section of the 18-mile tunnel on the Hetch Hetchy project, San Francisco's future source of water supply, was holed through on Nov. 26, 2,180 ft. east of Second Garotte shaft. This section is three miles long and extends from Second Garotte shaft to Big Creek shaft, from which points the two headings were advanced. The headings met with a grade discrepancy of 0.94 ft. and a difference in alignment of 0.25 ft.

At present the concrete lining of the Hetch Hetchy tunnels is being placed at only one point, but lining will be under way with two complete equipments at an early date. With one plant pouring two 8-hr. shifts and moving plant the third, the present progress is about 120 ft. per day, pouring sides and arch which contain a total of about 1½ cu yd of concrete per lineal foot.

On Dec. 1 the construction crews in the mountain division on the Hetch Hetchy project totaled about 1,200 men.

Canadian Institute to Meet

Announcement has just been made that the annual meeting of the Engineering Institute of Canada is to be held in Ottawa, Wednesday and Thursday, Jan. 23-24. The general meeting is to be convened at Montreal on the morning of Jan. 22, but the session there that day will be merely for the purpose of appointing officers and nominating scrutineers to count the officers' ballots. The regular sessions start the next morning at the Chateau Laurier in Ottawa. Wednesday will be devoted to reports of committees and to papers, with a banquet and smoker (somewhere in Quebec) in the evening. Thursday morning will be devoted to professional meetings with a visit to the Rideau Canal in the afternoon and a ball in the evening.

Engineering Societies

Calendar

Annual Meetings

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.: Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City: Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City: Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.: Annual Meeting, Chicago, Ill., Jan. 21-24, 1924.

ENGINEERING INSTITUTE OF CANADA, Montreal: Annual Meeting, Montreal, Jan. 22, and Ottawa, Jan. 23, 24, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich.: Annual Meeting (25th anniversary), Chicago, Ill., Feb. 25-28, 1924.

The Engineers' Society of St. Paul has voted to enter the Federated American Engineering Societies. Grover H. Wilsey, editor of the bulletin of the Affiliated Architectural and Engineering Societies of Minnesota, has been elected representative of the St. Paul society.

The Municipal Engineers of the City of New York had an illustrated lecture by Philip P. Farley, consulting engineer, New York City, on the Coney Island Public Beach and Boardwalk Improvement at their meeting Nov. 28.

The Engineers' Club of Kansas City, Mo., will hold its annual meeting Jan. 31, with a dinner dance as the social feature. A. C. Everham is president of the club, and Fred Johnson is secretary.

The Montreal Branch of the Engineering Institute of Canada at its meeting Dec. 6 enjoyed an illustrated lecture on "Irrigation in Brazil," given by Ira W. McConnell, vice-president of Dwight P. Robinson & Co., Inc., of New York City.

The Scientist Club of Indianapolis announces the nomination of the following officers for 1924: Earl Carter, president; D. J. Angus, vice-president; J. L. Wayne, secretary; and Arthur Hood, treasurer. The date of the annual election is Dec. 17.

The Albany, N. Y., Society of Engineers at its annual meeting Dec. 18 will have an illustrated talk on "Siphon Spillways" by George F. Stickney, consulting engineer, Albany, N. Y. Walter N. Mansfield is president of the society, and John W. Henry is secretary-treasurer.

Means, after graduation from Columbia University and service in the U. S. Department of Agriculture in irrigation and drainage study in France and Africa, was connected with the U. S. Reclamation Service, and later in private practice. He was engineer in charge of maintenance and operation on the Truckee-Carson project, consulting engineer of the Anderson-Cottonwood Irrigation District, and engineer on many soil surveys and irrigation investigations.

HENRY Z. OSBORN, Jr., who has been chief engineer of the Board of Public Utilities, Los Angeles, Calif., has opened an office in the Pacific Finance Bldg., Los Angeles, for consulting engineering practice. Mr. Osborn was formerly engineer of the street planning department of Los Angeles and chief deputy in the city engineer's department.

FRANK A. RAVEN has tendered his resignation as superintendent of public works of Albany, N. Y., a position he has held for two years, in order to return to consulting engineering work. Mr. Raven for many years has been consulting engineer for the Albany Felt and Ludlum steel companies.

R. STUART MCKENZIE, of Montreal, has been appointed consulting engineer to the Dominion Engineering & Inspection Co. of Montreal. Mr. McKenzie graduated from McGill University in 1901 and joined the engineering staff of the Canadian Pacific Ry. as chief draftsman in the bridge department. In 1910 he was appointed assistant engineer of bridges for the Grand Trunk Pacific Ry. At the end of two years he entered private practice as a consulting engineer, specializing in foundations and hydro-electric work. In 1920 Mr. McKenzie became associated with the Dryden Paper Co. as construction engineer, and designed, and built the hydro-electric plant at Eagle River, Ont. Later, for the Manitoba Power Co. he was field engineer on the 168,000-hp. hydro-electric development at Great Falls, on the Winnipeg River. Mr. McKenzie has been a member of the council of the Engineering Institute of Canada.

LOUIS BROWNLOW, for several years city manager of Petersburg, Va., has been appointed city manager of Knoxville, Tenn., and will take up his new work Dec. 15.

C. C. COTTRELL, manager of the Good Roads Bureau of the California State Automobile Association, has resigned to become chief engineer of the Western Willite Co., paving contractors, and will make his headquarters in Los Angeles. Mr. Cottrell has given valuable aid in promoting highway progress in California, having urged the conclusion of the controversy between the Victory and Lincoln highways and the designation of the Victory route in southern California, which also assures the completion of the Wendover cutoff. He was active in securing road revenue legislation abolishing the horsepower tax and substituting a nominal registration fee and two-cent gasoline tax. Mr. Cottrell was superintendent of highway construction and maintenance for the state of California from 1913 to 1917, assistant state highway engineer of Nevada for a time and state engineer of Nevada from 1918 to 1920. In Nevada he was responsible for the construction of 225 miles of highway.

Personal Notes

THOMAS H. MEANS, consulting engineer, San Francisco, and a member of the firm of Cope Rand Means Co., has been appointed consulting engineer of the Banta-Carbena Irrigation District in San Joaquin County, California. Mr.

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Interviews with Industrial Executives—3

Service Policy Aims at Proper Selection and Use of Steel Forms

AS A means of enabling contractors and engineers to get the best results from the construction plant they purchase the Blaw-Knox Co., Pittsburgh, manufacturer of steel products including forms for concrete, portable buildings, storage and measuring bins, and clamshell buckets, has set up a policy of service both before and after the sale of its equipment. This means, first, studying the work to be done and adapting the equipment to it, and, second, making the equipment function on the job to produce the best results. The details of this twofold obligation which the company has assumed are set forth in the following notes based on information *Engineering News-Record* has secured from Albert C. Lehman, president of the manufacturing organization:

This is the third of a series of "Interviews with Industrial Executives" in which Albert C. Lehman, president, Blaw-Knox Co., Pittsburgh, relates how the contractor is helped before work starts and while it is in progress.

The fourth interview will appear in an early issue.—Editor

buckets. In approaching a customer, therefore, our sales engineer is concerned not with a single detail of plant but with the contractor's general plant layout and the possibility of adapting our equipment to his needs. We often find it possible to make useful sugges-

After the sale has been consummated, Mr. Lehman explained, the company renders service to its customers by erecting the equipment in its own shop prior to shipment. In this way the field work is reduced to a minimum and there is no question as to shop workmanship. This is a service, it is claimed, which the average purchaser of steel forms or similar equipment which is dismantled and shipped knocked down, does not usually appreciate. This is true particularly of equipment designed to meet special conditions and where substitution for parts that do not fit is impossible.

ADVICE ON FORM ERECTION

At the time of delivery of steel forms to contractors the Blaw-Knox Co. furnishes complete erection drawings. An experienced erection engineer is also sent to the job to give the contractor such assistance as he may require in setting up his forms and getting proper results from them. This service man is kept on the job until the steel forms are performing in a manner satisfactory to both purchaser and manufacturer.

"As construction progresses," Mr. Lehman continued, "we revisit the job from time to time to see that the contractor's workmen are handling the plant economically and safely. We check up on the number of men working on a job and sometimes are able

TO INSURE PERFECT OPERATION ON THE JOB LARGE STEEL FORMS ARE ERECTED AT COMPANY'S SHOPS BEFORE SHIPMENT
Traveling forms for concreting 32-ft. tunnel, Niagara Falls Power Co.

"All the men who represent the Blaw-Knox Co.," Mr. Lehman explained, "sell service first and equipment second. We feel that service has the same large value to our customers as to ourselves. Consequently our service begins prior to the sale, continues while the equipment is being manufactured, and does not cease until the customer has practically finished his work."

PLANT LAYOUT STUDIED

Mr. Lehman was asked to amplify his statement concerning service prior to the sale of equipment.

"In the construction field," he replied, "our company supplies contractors not only with steel forms but also with overhead material-measuring bins, known as batcherplants, and clamshell

tions regarding the best combination of equipment for handling the work at the least cost and in the minimum time. The service-before-the-sale, therefore, may take the form of revamping the contractor's ideas about his general scheme of construction.

"In most large engineering projects there is, as a rule, no initial consideration given to the steel forms the contractor will use in his concreting work. There are in his mind, however, very definite ideas as to the results expected from the forms. This condition makes it necessary for the manufacturer's sales engineer to be able to analyze the customer's specifications, and, in consultation with him, plan equipment which will absolutely meet the conditions of the work to best advantage."

to point out to a contractor that his costs are higher than they should be. Our interest in the steel forms for concrete work does not cease until the job is completed."

ACCESSORY EQUIPMENT

The same sort of service that is given on steel forms for concrete construction is rendered for clamshell buckets and batcherplants. In the case of the buckets, the company stresses the importance of proper rigging in order to secure smooth working and maximum capacity. In the case of the batcherplants it is essential at the start to have the equipment erected properly.

"From a purely selfish standpoint," Mr. Lehman concluded, "it is profitable to any manufacturing company to give

Japan Will Be Heavy Buyer of Equipment and Materials

American Manufacturers Urged to Prepare Sales Campaigns for Demands Under Permanent Reconstruction Plans

Active buying of materials and engineering equipment under the Japanese permanent plan of reconstruction is expected to start early next year according to Luther Becker, chief of the Iron and Steel Division of the Department of Commerce, who urges American manufacturers to prepare their sales campaigns now "if they are to reap the full advantages of the opportunities offered." Next spring should see unusual activity in the Japanese trading market says Mr. Becker and these precautionary measures are urged in view of the keen interest and active preparation of our foreign competitors, notably the British and German.

"American manufacturers," said Mr. Becker, "are strongly entrenched in the minds of the Japanese trader and consuming public because of the good-will established during the war when their products for the first time gained wide recognition and approval. Our modern steel and ferro-concrete buildings proved their worth when they came through unscathed in the recent catastrophe at Tokyo, and to the Japanese people will stand as monuments to the fame of American practice and quality. It therefore obligates the American producer to back up this well earned reputation and come forward at this time of urgent need to co-operate with the Japanese in restoring their cities and factories."

RECONSTRUCTION PROGRAM

The reconstruction program for Japan involves two distinct phases the temporary and the permanent, the first of which has gotten underway. Because of the necessity for quick action in housing the homeless community during the coming winter the Government, through its Reconstruction Board, authorized the purchase of building materials that can readily be converted into cheap temporary buildings. In accordance with this plan the Japanese government has placed several orders in America and England for lumber and steel products and it is believed that additional orders will be placed in the United States.

Out of the deliberations and conclusions of the Diet Dec. 10 will come a permanent program which in interest and from the standpoint of trade value of the requirements for materials and plant equipment for reconstruction will far surpass, the Department of Commerce predicts, what has already been

the best it has in the way of information and guidance to its customers. The equipment manufacturer wants the user to make money; it wants him to use his equipment properly. The reaction from a policy of this sort is bound to be favorable to the company following it. In addition, the manufacturer benefits by bringing in from the field, through visits of his service men, ideas that may be utilized in future designs of equipment. By rendering service to contractors, therefore, we ourselves are taught real lessons in construction work and in the design and operation of the equipment with which it is carried on."

accomplished towards providing temporary relief. A permanent building code will have been evolved which will determine the types and size of buildings, kinds and quality of materials, more economical and efficient methods of construction, and fire-preventive measures.

For the larger buildings—government and municipal, office, hotel, bank and theater—use will be made, according to the Commerce Department, of the steel-frame and reinforced-concrete types of construction, which best withstood the unprecedented shocks by earthquake on Sept. 1 and the fires which followed. The relative high costs of steel and concrete construction in Japan will prohibit the adoption of these types for the ordinary native house.

More Bidding Time Needed

Manufacturers of equipment endorse C. G. Richardson's complaint (see "Engineering News-Record," Nov. 8, p. 783, and Nov. 22, p. 866) against necessity of hurried preparation of estimates on proposed work.

Elevating and Conveying Machinery

BY F. E. VAN SLYKE

Jeffrey Manufacturing Co., Columbus, Ohio

IN MANY CASES we have to refuse to quote on municipal equipment due to the short time allowed in which to prepare a proposal. Municipal engineers usually work out very elaborate specifications which do not always correspond to standard equipment supplied by various manufacturers. This often means alternate proposals, one in accordance with the engineer's specifications and one in accordance with the manufacturer's specifications. Then again, these proposals usually have to go through certain routine and a certified check must be furnished in every case. This all takes time and the four weeks mentioned could be extended, with advantage to all concerned, to six or eight weeks from the time the bids are mailed until the proposal is to be closed.

From the manufacturer's viewpoint a hastily prepared proposition can not be absolutely accurate in all details and a lot of guessing has to be done in arriving at a final price unless ample time is provided to figure out all of the details. On the other hand, the short time sometimes allowed prevents many manufacturers from even submitting a bid, as it is considered hardly worth while in view of the time limit.

From the purchaser's viewpoint a too short time means that they may not get the best possible equipment, as only a few bidders will go into the proposition. If the time had been lengthened they would probably have two or three times as many propositions, with ample time to give them all consideration.

Filler Plant Equipment

By H. W. HOSFORD

Norwood Engineering Co., Florence, Mass.

OUR attention has been called to Mr. Richardson's article in your Nov. 8 issue (p. 783) in reference to the shortness of time allowed manufacturers to prepare bids for municipal waterworks equipment. We wish to en-

Last Call!

MANUFACTURERS: Preparation of "Engineering News-Record's" Annual Editorial Review of Machinery and Materials—to appear in the first issue of the New Year—has begun.

If you have not already sent us a brief statement covering the outstanding improvements made in your products during 1923, it is requested that you do so at once. Otherwise the Review may omit adequate mention of your organization's contribution to the year's progress.—Editor.

dorse Mr. Richardson's views in this matter.

We manufacture and install equipment for mechanical rapid sand filtration plants. In a great many cases the engineer specifies that prospective bidders are to furnish detail drawings of their standard equipment, properly arranged to fit the proposed lay out. Many times the time between the advertising of the bids and the date set for receiving them is so short that it is impossible to do this. As stated by Mr. Anderson of the Chapman Valve Manufacturing Co. (see *Engineering News-Record*, Nov. 22, p. 866), there are many cases requiring special equipment on which we have to obtain prices from other manufacturers, which we are unable to do for the reason stated above.

Only recently we had occasion to bid on three different plants located in widely separated parts of the country, bids for two of which were received exactly the same day, and the third one on the following day. We had less than ten days to prepare all three bids. Needless to say, we were unable to bid on all of these jobs.

We believe that the engineers as well as the municipalities are desirous of obtaining as many competitive bids as possible on their work, and we cannot urge too strongly the advisability of allowing the different manufacturers more time in which to prepare their bids.

Business Notes

PAWLING & HARNISCHFEGGER Co., Milwaukee, manufacturer of excavators, cranes and machine tools, has recently appointed R. P. McCormick as Eastern sales manager with offices at 50 Church St. New York, and Stephen-Girard Building, Philadelphia.

NATIONAL STEEL FABRIC Co., Pittsburgh, has appointed H. D. Beaton Eastern manager, with headquarters in the Harrison Building, Philadelphia. Other recent appointments are those of W. L. Whitman as district manager, with offices at the Philadelphia address above referred to, and of C. S. Reno as district manager in charge of the company's office and warehouse at 523-5 West 33rd St., New York.

B. F. STURTEVANT Co., Boston, announces the opening of its new plant in Camden, N. J., to which the former Philadelphia division has been transferred. The new works include modern daylight shop buildings for the manufacture of sheet metal work involved in heating and ventilating equipment.

PORTLAND CEMENT ASSOCIATION, at its annual meeting in New York Nov. 21, elected the following officers: President, F. W. Kelley, Helderberg Portland Cement Co., Albany, N. Y.; first vice-president, Blaine S. Smith, Universal Portland Cement Co., Chicago; second vice-president, L. R. Burch, Atlas Portland Cement Co., New York; treasurer, John W. Boardman, Huron Portland Cement Co., Detroit. W. M. Kinney continues as general manager of the association.

FRANK H. DEWEY, for two years sales engineer of the Wood Hydraulic Hoist & Body Co., Detroit, has been made assistant general manager. He was connected with the Horizontal Hydraulic Hoist Co., Milwaukee, until that organization was absorbed by the Wood company.

Equipment and Materials

Twin Rotary Snow Plow

For clearing snow from highways, Monarch Tractors, Inc., Watertown, Wis., is manufacturing from designs prepared by its chief engineer, A. C. Webb, a twin rotary plow mounted on the front end of a tractor, as shown in the accompanying photograph. With other types of plow, the manufacturer states, there is a tendency, under certain conditions, to build up a wall of snow on either side of the roadway, forming a canyon out of which it becomes difficult to plow snow as winter progresses. The rotary plow, however, is designed not only to move the snow from the highway, but to throw it far to one side by means of a pair of revolving three-vane fans.

The Monarch rotary snow plow weighs about 4,500 lb., is 8 ft. in width, and is a self-contained unit powered by a Beaver heavy-duty industrial motor. The two heavy steel fans shown in the illustration are chain-driven at a speed of 350 r.p.m. Each fan can be disconnected independently by means of a twin-disk clutch. The fans run on Timken roller bearings.

The front shoe and rudder of the plow are designed to assist in steering, but the plow can be controlled by the tractor through push bars attached to the

crawlers. Movable guide vanes around the fan control the height and direction to which snow is thrown sideways.

Steel Sash Improvement

A recent improvement in continuous sash for factory and industrial buildings has been introduced by the David Lupton's Sons Co., Philadelphia, in the form of a new section of bottom rail for the Pond type of sash. In this new construction the bottom rail has its

outer face flush with the glass, so that water will run off freely when the sash is open. In the earlier design the rail had a horizontal flange on the outside and drip holes in this flange were depended upon to prevent pocketing of water when the sash was open and the flange therefore inclined downward. These drip holes would clog occasionally, retaining the water so as to cause corrosion of the steel. This condition is avoided in the new design.

One-Man Earth Mover Has Power Supplied by Tractor

Designed for use with a shovel, a ditcher or a crane attachment, the earth-mover shown in the accompanying

illustration has just been announced by the Insley Manufacturing Co., Indianapolis, and will make its initial appearance at the Good Roads Show in Chicago next month. The equipment is powered by a Fordson tractor and is intended as a one-man machine of low first cost as compared with other types of excavating equipment employed by road contractors, quarry operators and material-handling organizations.

By varying the attachments the machine may be made to serve as a 3-yd. shovel, a 3-yd. ditcher or a 3-yd. clam-shell bucket outfit.

Skip-Guard on Paving Mixer Prevents Accidents to Loading Crew

To prevent accidents to the crew on the loading end of mixers for concrete road construction the Chain Belt Co., Milwaukee, has developed an automatic skip-guard for its Rex pavers. Most of these accidents have been due to the lowering or falling of the loaded skip which, in the case of the 21-E machine, has a weight when loaded of 24 tons.

The automatic guard, illustrated herewith, consists of a strong pipe framework securely fastened to the lower main frame of the paver and completely encircles the loading skip. It is automatic in its action. When the skip is on the ground this guard rests on the ground and in no way interferes with the loading of the skip. As the skip is elevated the guard rises with it until

the guard attains a breast-high position, or a distance of 3½ ft. from the ground. At this point it stops and prevents any workmen around the skip from inadvertently getting under the skip while it is in its elevated position. As the skip returns to the ground for the next batch it lowers the skip-guard with it.

An effort is now being made to secure from liability insurance boards a reduction in premiums to users of the safety skip-guard.

Publications from the Construction Industry

Electric Motors—RELANCE ELECTRIC & ENGINEERING Co., Cleveland, in a 32-p. vest-pocket size illustrated booklet, offers some useful suggestions on how to select, install, and use electric motors.

Tractors for Snow Removal—HOLT MANUFACTURING Co., Peoria, Ill., has published a 16-p. illustrated pamphlet featuring the applications of its caterpillar tractors, equipped with plows, for removing snow from rural highways and city streets. The tractors are shown operating both with blade and with wing type plows. A point is made of the all-year-round usefulness of the tractor. It may be employed for snow removal in winter and for road building and general industrial haulage at other times.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Production and Materials Stocks in Ten Cities

Drop in Iron, Steel, Brick and Lumber Output—Cement Production Increasing—Dealers' Stocks Ample

Iron and Steel—Over 2,894,000 tons of pig iron were produced during November, against approximately 3,125,000 during the preceding month. The present rate is about that of the corresponding period in 1922.

The steel ingot output reached 2,969,012 tons during November, according to the American Iron and Steel Institute. October production totaled 3,382,986 tons and September 3,161,964, compared with 4,000,695 tons during May, which was the heaviest month of the year.

Lumber—The trend of the lumber movement of the country indicates a decided drop in production and shipments and a slight falling off in demand. The lumber movement, according to the National Lumber Manufacturers' Association, is shown in the following table:

	Four Weeks Ending	
	Dec. 1 ft. b. m.	Nov. 3 ft. b. m.
Cut	1,032,746,118	1,071,142,679
Shipments	939,826,553	986,126,293
Orders ...	903,601,237	920,159,103

Production is now about 2 per cent above normal, with orders 98 per cent and shipments 92½ per cent of normal output. Production, shipments and

orders for the four weeks ending Dec. 1, show declines compared with the preceding four weeks, and heavy gains over the corresponding period last year.

Cement—Production during the first ten months of the current year totaled 114,366,000 bbl., against 93,850,000, for the corresponding period in 1922, according to the Geological Survey. With a gain of 22 per cent in production and 17 per cent in shipments, compared with a year ago, a total of 4,597,000 bbl. were available, as a reserve stock for the nation, on Nov. 1, as against 4,149,000, on hand one year ago.

Brick—The report of the Common Brick Manufacturers' Association of America, as of Nov. 1, shows 306,922,000 burned brick on hand at yards throughout the country, compared with 307,633,000 for the month preceding. Many plants are closing down owing to seasonal conditions and during October the output was 163,000,000 brick with shipments at about 145,000,000. Stocks are being accumulated with the expectation of an active demand at the resumption of greater building activities in the spring. Aggregate orders on books have decreased about 8 per cent during the last thirty days, while actual increases in demand are noted in the East and Middle West. The shrinkage in orders is confined to the smaller cen-

ters, especially those in agricultural territories.

San Francisco—Stocks of building materials fairly large, with the exception of structural rivets and blue annealed steel sheets.

Los Angeles—Dealers behind on sewer pipe orders. All cement and lime plants active. Brick and tile demand steady and well supplied. Great quantities of lumber arriving at harbor from North Pacific coast. Supplies of all other materials sufficient to meet requirements.

Denver—Hollow tile and sewer pipe stocks low; other materials plentiful.

Minneapolis—Dealers report stocks of building materials ample in all lines, either as in local yards or warehouses or readily obtainable on short notice from nearby mills.

Detroit—Sewer pipe stocks decreased slightly during month; ample supply in local yards for present needs. Small stocks of hollow tile on hand; large deliveries require several days.

Chicago—Sewer pipe production just enough to satisfy small current demand. Stocks of all other materials ample.

Cincinnati—Sufficient dealers' stocks to take care of present demand.

New Orleans—Pine lumber stocks light; demand slow. Supplies of other materials fair; demand good.

Philadelphia—Small but ample stocks of sewer pipe. Hollow tile mill deliveries prompt, although dealers'

CONDITIONS OF MATERIALS STOCKS IN IMPORTANT CENTERS

Stocks on hand in approximate figures, examples (Common brick, Denver, 9,000,000); time required for delivery of carload lots to city job, example: (Lumber, Chicago, 30 (or 60) days); and stocks on hand in general terms, example: (Hollow tile, Cincinnati, plenty)

	San Francisco	Los Angeles	Denver	Minneapolis	Detroit	Chicago	Cincinnati	New Orleans	Philadelphia	New York
Sewer pipe	Stocks in good shape	Dealers behind with orders	Supply low	Ample	Stocks decreased slightly	Production sufficient to meet small demand	Stocks large	Fair; demand good	Small, but ample	Size 15 to 36 in., double strength scarce
Cement	Fairly well supplied	All plants active	Enough	Plenty in local warehouses	Plenty at mills	Very good supply	Sufficient to take care of demand	Plenty; demand good	Sufficient	Plenty; dealers' stocks small but ample
Lime	Stocks in fair shape	All plants active	Sufficient	Enough	About 15 to 20 carloads in warehouses	Plenty	Enough	No shortage	Plenty	Market well supplied
Common brick	Large reserves	Demand well supplied	9,000,000	Plenty in local yards	Ample supply in local yards	Def. nearly on par with mid-building season	Ample	Sufficient	Well supplied	Def. nearly on par with mid-building season
Hollow tile	Stocks large	Meeting demand	Stocks low	Obtainable on short notice from nearby plants	Stocks small; large def. requires several days	Slight drop in demand; stocks good	Plenty	Enough	Small stocks carried; del. prompt	Supply good; water deliveries prompt
Lumber	Plenty fir	Heavy shipments from North Pacific coast	15,000,000 ft.	Ample; demand kept up well	Moderate stocks in local yards	Def. take 30 to 60 days	Dealers' stocks sufficient to meet demand	Stocks light; demand slow	Yards well stocked	Mill del. very good; take 4 to 5 wks. from mill
Asphalt	Unlimited native reserves	Supplies meet steadily demand	Sufficient	Enough	Plenty	Ample	No market	Small demand; supply ample	Heavy reserves in N. J.
Structural steel	Plenty structural; rivets and b. & s. steel sheets scarce	Sufficient for requirements	Warehouses well stocked	Warehouse stocks ample	No shortage of local warehouse stocks	Fabricators at stocks of plain materials low	Demand small	Fair; good demand	Practically no dealers' stocks left; mill del. good	Structurals comprise bulk of demand

stocks are small. Warehouse stocks of structural steel very low; mill deliveries good.

New York—Brick deliveries in New York nearly on par with the mid-building season. Pine lumber mill deliveries very good; take only four to five weeks from mill. Hollow tile plants competing effectively with Western manufacturers on deliveries. Domestic building materials manufacturers have thus far been able to hold

their own against foreign competition, by reason of a greater knowledge of the requirements of the local builders.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 321 to 333, are the following:

Lock, Weston, Ky., U. S. Engineer, Louisville.

Factory, Toledo, O., Libby-Owens Sheet Glass Co., \$1,000,000.
Disposal plant, Canton, O., \$500,000.

Large Contract Let During Current Week

Among the week's announcements of contracts awarded in Construction News, pp. 321 to 333, is the following: Factory, Amelle, Md., to Austin Co., Philadelphia, Pa., \$2,000,000.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Dec. 6; the next, on Jan. 3.

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on white pine lumber, free on cars at mill. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97-17). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

Unevenness continues to be the chief characteristic of the general market, particularly during the present inventory season. Few buyers are purchasing beyond immediate needs, and stocks of materials are being kept as low as possible. Production has fallen off in several of the basic commodities, particularly pig-iron and cotton goods. Increased activity, however, is noticeable in certain branches of the leather industry. Continued heavy car loadings indicate the handling of a vast amount of merchandise.

Few price changes occurred during

the week in the basic building materials. Dallas reported an increase of 20c. per 100 lb. in steel structurals and 2c. per gal. in raw linseed oil. Minneapolis also quotes a rise of 2c. per gal. on linseed oil, due to lighter flaxseed receipts, the year's crop being about marketed. Chicago, however, reported a drop of 10c. per 100 lb. in structurals; Dallas, a decrease of \$3.50 per ton in hydrated finishing lime and Atlanta, a decline of 1c. per gal. in linseed oil.

The iron and steel situation is briefly outlined as follows: Pig-iron sales smaller. No. 2 foundry iron \$21@22

per gross ton, Birmingham. Coke higher. Finished steel prices firm. Mills receiving inquiries involving large tonnages. Improved railroad demand for steel plates. Oil-storage tank plate requirements small. Structurals continue at \$2.50 base, with \$2.40 quoted on exceptionally large tonnages; bars, \$2.40 per 100 lb., Pittsburgh. Unfilled steel tonnage of the U. S. Steel Corp., Nov. 30, totaled 4,368,584 tons, against 5,035,750, Oct. 31, and 7,403,332 on Mar. 31, 1923. March showed the heaviest unfilled tonnage of any month this year.

Good Will Toward Men

ONCE MORE Christmas comes. Once more we do service to that spirit of good will which is the essence of Christmas. In its material form that spirit is strong in the American people. Never was there so charitable a people; never was there so charitable a period. Out of our great abundance we give freely and the hungry and the stricken of the world can bear witness to our good will toward men. In the Christmas time when this material evidence of good will is so strong may we not consider the need for another kind of good will that is just as surely a part of the Christmas and Christian spirit as the open purse and the generous hand. Are we in danger of

becoming intolerant? Are we forgetting that respect for our fellows' opinions and beliefs becomes us and helps them just as much as do less irksome aids for the needy and succour for the hurt? We should be a tolerant people. The founders of our nation fled from the intolerance of their fellows to set up here a government where any man might believe as he would and where the majority should rule. On this principle we have prospered. Let us beware lest we forget. In private difference and public quarrel the Christmas time is a good time to take stock of prejudices and to weigh motives. Good will toward men! Charity in act, yes; but more, charity in thought.

A Chapter Closed

IN TAKING over the plant of the Proprietors of the Morris Aqueduct, Dec. 15, Morristown, N. J., closed a chapter in water-works history. Morristown was one of the sixteen municipalities in the United States which had a public water supply at the close of 1800. At that time 15 of the 16 works were privately owned, the single exception being Winchester, Va. One by one 14 of the 15 cities changed to public ownership until from 1896 to a few days ago Morristown was the sole example to the contrary. Why Morristown should have clung so long to private ownership after the other fourteen municipalities changed we cannot say unless its part was to be the exception that proves the rule or unless it was well satisfied with the service rendered by the Proprietors of the Morris Aqueduct. However this may be, four years ago the people of the town voted decisively for municipal ownership, which seems to have been achieved on unusually favorable terms for the public, as may be seen from the statement of the engineer-mayor of the town printed elsewhere in this issue, together with some data regarding the sixteen water-works of the eighteenth century.

The Chicago Typhoid Outbreak

BOIL-THE-WATER notices in Chicago bring back old days. A recent outbreak of typhoid has been confined to the Hyde Park section of the city. It has no adequate explanation as yet. The Health Department declares that the water supply is the cause, specifies the overflow of sewage at one of the Sanitary District pumping stations, a reversal of flow in the Calumet River, outward winds, and recent offshore bacterial studies in support of its conclusion. But on Aug. 11, the whole Chicago River was in reverse flow for six hours, sweeping into the lake many times the volume

of sewage that's alleged to have escaped from the pumping station about Nov. 1 but without notable effect on the city's typhoid. Moreover, supposing mass infection in marked degrees resulted from the relatively minor pumping station overflow, how explain why of intakes two hundred feet apart the water from one alone should carry typhoid to the district it supplies? Chlorination and, it seems, water sampling and tests, are done by the Health Department. In the light of present confusing theories and inadequate data, Chicago should make an immediate and searching study, by means of competent experts, to determine whether it is not imperative that immediate steps be taken to join the other cities on the Great Lakes in providing water filtration.

The Roll of Shame

STATISTICS of the motor car killings in the big cities of the country in 1922, just issued by the Bureau of the Census, show that the evils of excessive traffic are increasing. For the 72 cities over 100,000—counting each borough of New York City as a city—the average deaths from automobile accidents per 100,000 population was 16.2 in 1921 and 16.9 in 1922. In fifty-two cities the number of deaths increased and in twenty they decreased. The worst offender continued to be Los Angeles, which not only topped the list with 29.5 deaths per 100,000 but exceeded its own record killing of 1922 by 2.4, dropping only slightly below its rate of rise of 3.0 for each of the preceding three years. Two smaller cities, Camden and Memphis, came next but they apparently had bad years for their prior records were not so high. The same is true of Atlanta and Baltimore which are fourth and fifth, with the same rate of 24.7. Low rate cities—below 14.0 and consistently so—are Albany, Fall River, Indianapolis, Jersey City, Milwaukee, New Orleans, Bronx and Queens

boroughs in New York, Omaha, Philadelphia, Portland, Ore., Richmond, Va., Seattle, and Spokane. There is something more than coincidence in the continued high or low rate of automobile killings in a city. A visit to the two cities and a knowledge of their people tell in themselves why Los Angeles is the biggest killer and Philadelphia among the smallest. Fair traffic rules honestly observed and rigidly enforced may not save all the lives that are being lost from the coming of the automobile but they will save many. The cities who top this roll of shame must sooner or later come to see it.

Train Spacing or Engine Signals

FAILURE of the engineman of the 20th Century Limited to observe and act upon the automatic signal indications in last week's accident at Forsyth, N. Y., is being used, and rightly so, to emphasize the need of automatic train control, but in so doing it is quite possible that another important feature of the accident will be entirely overlooked. It is the evidence of how insufficient was the space interval between the sections of the train. The flagman was only a short distance from the rear of his train when the following section passed him, so short a distance that any effort he could make was fruitless.

The lack of such space interval between trains is not peculiar to the Forsyth accident; it is common to all of our railroads which handle a heavy passenger traffic and is the result of the more crowded railroads' inability to handle the peak load passenger traffic with their present trackage without running passenger trains in sections close to each other or causing the passengers considerable delay and inconvenience. The operation of regular trains in sections is not inherently wrong. In fact it is safer than running extra trains. The wrong lies in operating the sections close together in order to increase the peak capacity of the trackage and to satisfy the demand that all sections of an advertised train reach their destination as close as possible to the schedule time.

The result is that we have trains traveling at 60 miles an hour only four or five minutes apart, *sometimes less!* Under such conditions no amount of human or mechanical vigilance will prevent a repetition of the Forsyth accident. Automatic train control will reduce the number of such accidents but will not prevent them. Moreover such a system of train control is bound to decrease the vigilance of the enginemen and to increase their dependence on a mechanical device that by its very nature will not be put to the test of operation until the very time that it is most needed. The existing automatic train control devices are largely new and untried. Legislation making their use obligatory before they have been given severe tests under actual operating conditions might easily result in increasing rather than decreasing the number of rear-end collisions or similar accidents.

The road to accident prevention lies in so increasing the space interval between passenger trains that when a train is delayed or stopped there will be sufficient time for the crew to protect their train against the failure of the following engineman to observe, or of the mechanical devices to respond to, the danger. And that means some reduction in peak-hour track capacity and some inconvenience to those passengers who do not buy the early reservations on the popular trains.

Reclamation's Trial Balance

IN THIS issue appears the concluding one of a series of nine articles begun Oct. 25, in which men of special knowledge have reviewed the great enterprise of federal arid-land reclamation. The preceding articles outlined its development; this week Congressman Addison T. Smith of Idaho, himself a settler on irrigated land and now chairman of the House committee on irrigation of arid lands, sketches some future needs and possibilities. Together, the articles direct the reader's thoughts to the present problems of reclamation and the broader problem that lies just ahead.

A large responsibility confronts the American people. Reclamation of land by national enterprise has reached the end of an epoch. The easily irrigable lands, the readily available waters and the eager settlers of prior years are no longer at hand. Much land still awaits reclamation, but it presents new and far more difficult conditions. Are we to go forward? And are we to do so by the methods of the past? The people must decide. The issue involves the sound growth of the nation.

Hitherto the subject has not received much attention from the men in the eastern half of the country. Most of them have thought of it hazily as the building of great works somewhere in the West. Nor for that matter has the average Westerner been adequately familiar with it, for land reclamation is vast and complex. A wise policy, however, must root in sound public opinion. It is our hope that the articles now concluded may help to disseminate the information from which such opinion may be formed.

The future attitude of the country toward reclamation involves questions of great moment, which we hope to discuss briefly later on. Our present concern is whether the past twenty years' work in reclamation has been successful or not. Has the enterprise been mismanaged, as the Secretary of the Interior claims? This must be answered before it is possible to think constructively of future policies. The answer is found in the facts set forth in the articles, and in supplementary field observations reported in a series of letters written from a staff survey, which also closes in the present issue.

Reclamation is shown to be an over-all success. It has developed thousands of farms and homes, and produced hundreds of millions of dollars worth of food supplies. It has enriched the West in values and in money by an amount many times greater than the sum invested by the nation. It has done its work at moderate cost, and by processes of high efficiency and virile honesty. It faced extreme difficulties, and dealt with conditions and problems incomparably greater than those of private irrigation. Federal reclamation took up those developments that were too difficult for private enterprise; it watered the land at no greater construction cost than private undertakings, at equal or lower operating cost, and with even-handed fairness and efficient service to the thousands of farm families for whom it was undertaken. Seen at large or in detail, the facts consistently show that planning was far-sighted and able, that construction was of high quality and low cost, and that operation was efficient and economical.

This is the broad showing of reclamation's trial balance. There have been those who impugned the record

on the ground that some structures were too costly and others not good enough. There have been those who pointed with reproach to a leaky reservoir bottom in gypsum, to a canal or a dam damaged by landslips, to valves and conduits which wore out rapidly while serving under unprecedented conditions, to wells which did not yield the expected amount of water, to unforeseen gas and water troubles in driving a tunnel, or to occasional cost figures exceeding anticipations based on different conditions. Fair consideration of all the facts, we are sure, will lead the impartial observer to dismiss many of these reproaches as unfounded, and to accept the others with feelings of relief and surprise that so few mischances, errors and unforeseen obstacles should mark the history of a great pioneer undertaking.

The facts also show that both the operation and the construction phase of reclamation are permeated with engineering requirements to a degree that makes engineering direction essential to good results. This conclusion applies throughout, from project management to direction of the Service as a whole. Herein will be found one of the important lessons for the future, and a damning reflection on the course now pursued by the Department of the Interior in resorting to politician management in the guise of "business administration." Political exploitation of farm development spells destruction.

Reclamation has had its troubles, however, and has them today. When it invited the pioneer to take up its lands, it failed to remove from his path the traditional hardships and often miseries of pioneering; and all the curse of those hardships and miseries has been visited upon it. On the urgent plea of land owners and promoters who desired the government to better their fortunes it went out into the West and built dams and canals, only to find itself drawn into a struggle against the cupidity of the owners, who seized upon the increase in land value without paying for the works. It not only lost the struggle but in addition it made enemies of those with whom it fought. Reclamation was planned to subsidize the settler seeking a home on the land; in a large measure it has subsidized the money-lender and the land speculator instead.

Moreover, weakly or sympathetically reclamation went far outside its field. Though intending to do no more than build irrigation works, it soon became a retailer of water; and, unlike a public-utility company, it was burdened by its governmental character and by interference from Congress and the executive department to the degree that it was unable to collect its water charges regularly. Thus it fell into the part of philanthropic guardian of the irrigators. It was wholly unequipped to deal with a hundred thousand obstreperous wards, who would not operate their water-supply, would not drain their lands, and would not co-operate in developing the farming methods needed to suit the special conditions of their situation. And, while still in this guardian position, it encountered an agricultural crisis of unparalleled severity, all of whose evil effects were charged against the sins of reclamation. Normal governmental mechanism is not constructed to cope with such difficulties.

At the bottom these evil results are chargeable to reclamation itself. To carry out its purposes under the conditions that had to be met it needed to apply a more fatherly care of its wards, coupled with effective control. Neither was provided for in the law or in the

administrative policies based on it. Departmental government along conventional lines is not adapted to paternalistic functioning. Now that we may look back at the experiences of a generation it seems clear that in undertaking to assure the growth and good fortune of far-spreading pioneer communities as it did, without co-operation of local government, the federal government engaged in what was really a colonial adventure, one to which ordinary administrative methods were wholly unsuited.

The faults back of this condition are not due to engineers, however. They were committed by the government itself, by the statesmen and officials of administration after administration. If what was done is an indictment, it indicts the governmental principles on which reclamation has been built up. It indicts bureaucratic and Secretarial management, and demonstrates that technical control must be supreme if so great an enterprise is to make consistent progress. For many reasons, therefore, a new reclamation policy is called for. To spend the nation's wealth for further reclamation development until such new policy is established would invite disaster.

In the meantime it is gratifying to observe that the present reclamation projects have largely worked through their difficulties, and as a whole no longer constitute a problem. It is true that the reclamation farmer is not in a comfortable position, but he is only in the same plight as other farmers, and for the same reasons; the general farmer needs help but he cannot be helped by tinkering with reclamation debts. The difficulties and hardships due to reclamation itself have been overcome. There are, however, detail problems in the various projects. Most of these problems will work out successfully under present laws and administrative methods. Others may be relieved by improving the present law and strengthening or broadening the local administration accordingly.

Such adjustments as these are required: Individual deferment of the government debt of some farmers is called for as a matter of sound and fair business. Blanket deferment such as legislated in the past two years and again proposed in Congress has been shown to be thoroughly unsound, and in the present juncture would be little short of calamitous; but Congress should authorize individual extension of payments for cause, on businesslike terms. Provision should be made for removing serious injustices now existing, by giving authority to adjust the debts according to variations in land quality and climate. Authority should be given for writing off certain lost investments that have been made in the course of the reclamation development, in order that the clouded title of some of the projects may be cleared. Finally, agricultural promotion work is needed on the projects, to support the government's desire that the projects become prosperous farming communities and its demand that the loans be repaid.

Under capable engineering management, such measures will assure the fuller success of the reclamation development created by the labors of twenty years. It is for Congress to enact these measures into law and thereby take the final step in realizing upon the country's reclamation investment. It is also for Congress to give tardy recognition to the engineering responsibilities of reclamation by requiring the Service to be under direction of a competent technical authority and preventing its being the plaything of party politics.

Fast Hydraulic Filling of the Wichita Falls Dam

Monthly Lifts of 12 Ft. Each Were Made with Material Consolidating Immediately and Supporting Dragline Throwing Up Levees for Pool

BY ALBERT S. FRY AND R. A. THOMPSON AND O. N. FLOYD
Morgan Engineering Co., Memphis, Tenn. Chief Engineer and Assistant Chief Engineer Wichita Co. Water Improvement District 1, Wichita Falls, Tex.

THE HYDRAULIC fill storage dam of the Wichita County Water Improvement District 1, 40 miles west of Wichita Falls, Tex., is practically completed. As noted in *Engineering News-Record*, June 21, page 1080, the main structure is 7,500 ft. long, has a 100-ft. maximum height and contains 1,500,000 cu.yd. of fill. of which 1,235,000 cu.yd. was placed by hydraulic dredge and the remainder by teams. A second article, in *Engineering News-Record*, June 28, page 1118, described the flooded dry-fill diversion dam 15 miles

long, which carry the stream flow during construction and which will later control the outflow from the reservoir, were located in the south bluff. It was necessary to place the conduits in this location in order to secure a good foundation although so doing required the excavation of a large volume of material from the side of the hill. The upstream entrance to the conduits is protected by precast oval-shaped reinforced-concrete guard bars. The outlet is designed to provide for the control of the hydraulic jump and reduction of the

STORAGE DAM OF WICHITA COUNTY WATER IMPROVEMENT DISTRICT 1

downstream from the storage dam. This third article deals mainly with the construction of the storage dam which was carried up at a rapid rate by means of an electrically-operated hydraulic dredge built within the reservoir where was found an almost ideal material for quick consolidation. Wooden bulkheads retained the pool on the upstream side; on the downstream side it was retained by levees thrown up by a small dragline excavator. Riprap on the semi-circular spillway slope consists of a thick rubble paving of limestone cap rock found on the site while on the water face of the main dam an 18-in. hand-placed layer of the same material was used.

The storage dam is located 8 miles from Mabelle, the nearest station on the Wichita Valley R.R. At the beginning of construction, a road was built from this point to the dam over which to transport equipment and materials. Most of this road was on the top of a divide and no grading was required except at a few steep places which were cut down by a 1-cu.yd. gas crawler tractor shovel as it was being moved in.

Conduits—At the dam site the river channel is close against the south side of the valley and the six 7-ft. circular reinforced-concrete outlet conduits, 430 ft.

velocity of the water from the conduits to a safe velocity for the river channel below the dam. All corners around which water must flow were rounded to reduce friction losses.

Four of the conduits, built for construction purposes only, will be sealed after the main dam and spillways are completed. It was necessary to build six conduits to provide capacity for passing such floods as might occur during construction, and this provision has proved ample. The two center conduits, which are the permanent service conduits, are each fitted with two cast-iron gates with bronze facings to control the outflow.

Air ducts were constructed for the two service conduits to introduce air below the point of regulation of the main gates to prevent disturbances in the flow through the gates and injury to the gates themselves. Each duct consists of a concrete well 3 ft. square, built on the downstream side of the gate tower.

Core Trench—A core trench was excavated under the dam for its entire length except across the river channel and the service spillway. Across the river valley this trench is 20 ft. wide at the bottom, has side slopes of 1 to 1, and was excavated to the level of the bottom of the river. Steel sheetpiling was driven in the center

of this trench to a penetration of from 4 to 5 ft. into a shale formation. The sheetpiling was driven from the north side across the river valley and channel to the south toward the conduits.

After the river channel had been closed off, following the driving of the sheetpiling, an embankment was built with teams out of carefully selected material, suitable for core purposes, on the lower side of and against the piling for support when the lake was formed upstream for floating the dredge. This fill was built in wagon lifts, carefully wetted and puddled next to the piling. The subsequently placed hydraulic core extended entirely over and encompassed this material, care being taken to be sure that the material used to back up the sheetpiling became thoroughly saturated and incorporated into the core of the dam as the hydraulic fill was placed. The river channel was closed at a time when the river was practically dry and after the conduits had been completed so that whatever flow there was in the river was diverted through the conduits.

A cutoff trench was excavated under the part of the embankment beyond the river valley into impervious clay or shale. The depth of this trench was sufficient to insure the intercepting of any pervious strata through which the water might flow under the dam. This trench was filled with core material placed by the hydraulic dredge for the hydraulic fill section of the dam and was filled with selected material and puddled to the height of the original ground surface for the section of the dam constructed by teams.

Hydraulic Fill—Material for the hydraulic fill was dredged from the river valley above the dam. The material in the borrowpit is mostly a rather fine sand containing probably 25 per cent of clay and very fine sand suitable for core purposes. Ordinarily the dredge takes a cut of this material from 30 to 45 ft. deep and in this depth there are usually encountered one or more layers of stiff red clay from a few inches to a few feet thick. Occasionally small layers or pockets of gravel are struck and sometimes a few large boulders. The accompanying table shows the results of mechanical analyses of material in the slopes of the core and the dam:

MECHANICAL ANALYSIS OF MATERIALS

Sieves	Near Outer Slope	Midway Between Core and Slope	Near Core	Core
Through 1-in. mesh and on 10-mesh	0.0	3.0	9.4	0.0
Through 10-mesh and on 20-mesh	1.1	4.0	2.6	0.0
Through 20-mesh and on 40-mesh	20.4	41.2	20.0	0.0
Through 40-mesh and on 80-mesh	59.6	46.0	48.1	2.7
Through 80-mesh and on 200-mesh	16.3	4.6	8.5	32.1
Through 200-mesh and on 0.04 mm.	2.6	0.2	1.4	23.1
Smaller than 0.04 mm.	0.0	0.0	0.0	42.1

The figures given are the average from three samples, taken Dec. 15 and 31, 1922, and April 1, 1923. The material retained on the 10-mesh sieve as shown in columns 2 and 3 was largely clay balls. Samples of the sand or slope material taken from time to time as the dam was built up showed no particular change but the samples of the core showed that the material in the core gradually became coarser as the dam rose and the core pool became narrower. This material makes a compact and stable fill. A team can be driven over it either wet or dry without sinking into it more than an inch or two.

Ball Test—After the large cutoff trench was filled, there was a slight excess of core material which, of course, was desirable as it eliminated danger of sand slides into the core. While the core was from 80 to 100 ft. wide and the cutoff trench was being filled a 6-in. cast-iron ball would sink into it from 12 to 17 ft. When the dam had reached a height of from 25 to 30 ft., this softer material had been crowded out and the ball showed a penetration of only 6 to 8 ft. below the water surface. The penetration decreased as the height of the dam increased and near the top the ball would sink only 2 or 3 ft. As the top of the dam was approached, the proportion of core to the balance of the fill diminished considerably. This caused more core

INLETS TO FOUR CONSTRUCTION AND TWO SERVICE
CONDUITS THROUGH THE DAM
Rounded bars guard entrance to conduits having rounded ends

material to be wasted which in turn caused the core to be stiffer as the fine particles went out first.

On the night of April 11 the core pool broke through or over the downstream levee near the north end of the dam, making a gap 24 ft. deep at the toe of the slope and extending about 15 ft. back into the core. A section of the core about 15 ft. high was exposed. This stood up in excellent shape. The core was very stiff and broke off in large blocks as the supporting sand was washed away. The core stood with face 8 to 12 ft. high practically vertical except for the large blocks at the toe which had broken off and slipped down. A cubic-foot sample weighed 140 lb.

Dredge Operation—While the conduits were under construction, a launching pit was excavated by a drag-line machine in the floor of the river valley a short

a million yards, the shell was so badly worn that sectional cast-iron liners were made and bolted in all the way around so as to enable the same shell to finish the job.

The dredge has a daily capacity of 10,000 cu.yd. and pumped about 200,000 cu.yd. per month for the first four months. After the dam became high and narrow the various delays reduced the monthly output considerably. The vertical rate of progress on the dam for the first five months was about 12 ft. per month. This decreased to about 8 ft. per month during the latter stages of the work due to delays and increased length of dam. With the possible exception of the river section of the Taylorville Dam on the Miami Conservancy District, it is believed that no other hydraulic fill dam has been brought up so rapidly. In spite of this unusual

HYDRAULIC FILL STORAGE DAM UNDER CONSTRUCTION

Bulkheads were used on upstream side and levees on downstream side. Concrete tower built the six conduits and the gate and air tube shafts. Sheerboards were placed along edge of pool to prevent formation of tongues of sand.

distance above the dam, and a hydraulic dredge was assembled in this pit. The dredge is 111 ft. long and is equipped with a 42-ft. beam and a hull 9½ ft. deep. Northwest fir was used in building the hull. A ladder 75 ft. long, built up of 30-in. I-beams and cast-steel saddles carries the cutter head and suction pipe. The two wooden spuds are 26 in. square and weigh 9 tons each. The dredge was operated with electrical power brought in over a transmission line from Wichita Falls 41 miles away. Transformers located on the south side of the river reduced the 38,000-volt current to 2,300 volts. Twin submarine cables carried the power from the transformers to the dredge. The dredge was launched May 30, 1922, and began operating on Sept. 11, 1922.

The dredge pump is of the centrifugal type direct-connected to a 1,600-hp. motor and is run at 360 r.p.m. The pump is designed for necessary pipe friction plus a maximum lift of 65 ft., the difference in elevation between the top of the dam and the surface of the ponded water during the final stages of construction. The manganese-steel pump shell has cast-iron side liners which can be replaced when worn out. The runners are cast steel and range in size from 54 to 64 in. In the beginning the smallest size was used and the larger ones were put on from time to time to take care of the increased head as the dam became higher and longer. When the dredge pump had handled almost

speed, however, there has never been the slightest indication of any lack of consolidation of the core or slopes, and it is the opinion of the engineers on this dam that a hydraulic fill dam, if properly handled, will consolidate as fast as it is practicable to deliver the material and build it up. The slope material is as compact the moment it is placed as it ever will be and the core consolidates by the water being forced up through the newly deposited mud because the weight of any good core material is at least twice as heavy as an equal volume of water.

Pipe Experience—The discharge pipe was made up of 20-in. 10-gage riveted-steel pipe, which is unusually large for hydraulic dam construction. Wooden pontoons were used for floating the pipe across the lake above the dam. The shore pipes were slip-joint sections 20 ft. long. The pontoon pipes were 32 ft. long and were connected by rubber sleeves.

As the principal wear is on the bottom third of the periphery the pipes were turned so as to even up the wear. The average life of the shore pipe on this job was about 600,000 cu.yd., but even after that much service patches were welded over the holes, and the pipe gave considerably more service out near the end of the lines where the pressure was not great.

The velocity through the pipe line was from 10 to 15 ft. per second. Apparently 10 to 12 ft. per second would be sufficient, but there was no provision for con-

trolling the speed of the motor and a runner large enough for the longest line of pipe had to be kept in the dredge pump. Therefore, on the short lines it was inevitable that too much water was pumped.

During the first stages of construction, the fill material was confined by wooden bulkheads about 4 ft. high and stepped to form the required slopes. It was later found to be more advantageous to confine the material by a levee thrown up by a small dragline machine operating on the outer edge of the fill. However, because of the amount of lumber purchased for bulkhead construction, the bulkheads were continued in use on the upstream slope and the dragline levees were used on the lower slope. The material is discharged from the pipe near the outer slope of the dam and flows toward the core pool in the center of the dam, grading hydraulically. The width of the core at any elevation has been

discharge channel leads into a deep pool, the bottom of which is some 50 ft. below the present ground surface, 5 ft. below river bed and 90 ft. below the spillway crest. The downstream side of the pool, formed by the natural shale which occurs here, was excavated to a $\frac{1}{2}$ to 1 slope. Water flowing over the spillway will discharge into this deep stilling pool and will then flow off over the natural shale rim of the pool, down the canyon into the channel below.

The design of this spillway was adopted after a consideration of various types of structures, and was influenced to a considerable extent by the character of the material through which the canyon leading from the spillway down to the river is cut. This material is a very heavy shale with occasional thin layers of sand and limestone. When exposed, the shale disintegrates slowly to a shallow depth and it is expected that when

SEMI-CIRCULAR SERVICE SPILLWAY BEFORE ERECTION OF HOLLOW DAM AT CREST

After dragline was used in excavating the slope the heavy piprap was placed and the interstices were filled with concrete.

Mixer plant at left chuting concrete to place. Shale (at left) will not be excavated but left to disintegrate.

made the same as the height of the dam above that elevation.

During the early stages of construction, the pool was drained by means of a timber spillway over the side of the embankment into the lake. This proved unsatisfactory, however, as the dam attained size, and vertical wells or sumps built up as the height of the dam increased were constructed within the fill with pipe outlets to the upstream toe to provide for the return of the pool water into the lake. Inasmuch as all of the water is returned to the lake above the dam there has always been sufficient water to maintain operations even during the driest season.

As the embankment and core pool rose and narrowed it was necessary to use care to prevent tongues of sand from shooting out into the pool. Boards were placed about 5 ft. back from the margin of the pool to deflect the water, reduce velocity and prevent sand being carried out into the core.

Wooden racks bordering the pool were used for storing discharge pipe when not in use.

About 4,500 ft. of the main dam containing 215,000 cu.yd. lie north of the hydraulic fill. This is a low section averaging about 20 ft. in height and has been placed by teams and dump wagons using elevating graders.

Service Spillway—The service spillway is located across a canyon just north of the main body of the dam. A semi-circular hollow concrete dam forms the crest of the spillway from which a sloping paved

there is a flow over the spillway the disintegrated shale will be washed away and a new surface of shale will be exposed to the atmosphere after the flood has passed. This action will occur after each flood, but many years will elapse before the bed of the canyon below the spillway is cut down to river level, and there will be ample time for observing conditions and taking such measures as may be necessary to prevent destructive action at the lower end of the spillway.

The depth of the stilling pool was determined by the velocities which will obtain in the canyon below the spillway when the natural surface below the spillway cuts down to the bottom of the stilling pool, the depth being such that the velocities in the canyon, when this has taken place, will not be sufficiently great to cause damage.

The excavation for the service spillway was made by dragline and gas shovel. The dragline has a 70-ft. boom and $2\frac{1}{2}$ -cu.yd. bucket operated with distillate oil. All the material that could be reached conveniently by a dragline was removed by that method. Operating on the upper rim of the spillway, the excavated material was placed in a spoil bank above the spillway and some of it was later loaded with the gas shovel onto wagons and used in the wings adjacent to the headwalls. Material taken out with the dragline from the lower side of the spillway was wasted below. The dragline and shovel worked in conjunction, each machine being used when it could be operated to best advantage. Long lines were used on the dragline bucket, which

enabled it not only to remove material from the bottom of the excavation but also to strip the slopes of the excavation from the bottom.

The rock for the rubble paving for the floor and slopes of the spillway came from a limestone stratum of cap rock about 30 in. thick found near the spillway. This rock was broken out with light charges of black powder and required very little stripping before being quarried. The rock was placed with the dragline from which the bucket had been removed. Holes were cut into the rock with a jackhammer for inserting hooks to insure safety in placing.

The concrete in the floor cutoff walls and slopes of the spillway to a height of about 10 ft. above the floor was placed from a mixer located on the lower side near

near the surface where the spillways are built and no appreciable volume of stored water will be lost.

Riprap—The upstream face of the dam is protected by a layer of limestone riprap 18 in. thick placed by hand. The spaces between the stones are rammed full of spalls with a sledge down to the 8-in. gravel blanket which underlies the riprap. This riprap will give better protection and is less expensive than a thicker layer of rock loosely dumped. The rock for the riprap was quarried from the cap rock ledge of limestone in the vicinity. A gravel blanket with minimum thickness of 8 in. was placed on the upstream slope of the dam under the riprap. It was obtained from a gravel bed on the slope of the hill at the north end of the hydraulic fill.

the center of the circle. Above the 10-ft. level the concrete was placed from a movable mixer and tower on skids located at five set-ups just outside of the upper toe wall of the hollow section. Concrete from the mixer was transported to the top of the slope in buggies and allowed to flow down the slopes as the voids in the rock were filled. The flow was directed by men with shovels and other men with rods worked the concrete into the open spaces in the rock. The spillway concrete slope paving was divided into sections about 10 ft. wide to facilitate construction. A slightly wet mixture of 1:2:4 concrete was run in first to fill up the voids between the rocks. This was followed with a rather dry mixture placed on top and troweled into place, giving a fairly smooth surface.

Emergency Spillways—The emergency spillways, located at the extreme north end of the dam, consist of two sections of earth dam, for which the crest has been lowered, confined by headwalls so that they will be the only parts of the dam to give way during extraordinary floods. The first emergency spillway is 70 ft. wide and its crest is 7 ft. below the top of the dam. The second emergency spillway is 335 ft. long and its crest is 4 1/2 ft. below the top of the dam. The riprap paving which is used on the upstream face of the dam is extended over the upper slope of the emergency spillways. The water will be flowing over the service spillway 8 ft. deep before the first emergency spillway would go out and 10 1/2 ft. deep before the second one would come into action. In the event that the emergency spillways are washed out they will be washed down only to the underlying limestone rock which is

Materials—Coarse aggregate for the conduits was crushed limestone shipped in by rail from Chico quarry, about 125 miles south, and was hauled from Mabelle station to the dam in wagons. The coarse aggregate for the concrete for the spillways was obtained from a pit located at the end of the hydraulic section of the dam. A gravel washing and screening plant was installed and the bank gravel washed and screened. The sand used in the spillway concrete was a by-product of this washing.

R. A. Thompson is chief engineer for the district and in direct charge of the work. O. N. Floyd is assistant chief engineer. The Morgan Engineering Co. is consulting engineer, L. L. Hiding, president, giving immediate supervision. The general contractor for all of the work is the Callahan Construction Co., of Dallas, Tex., from whom the Puget Sound Bridge & Dredging Co. of Seattle, Wash., subcontracted the hydraulic fill.

Motor Vessel Use Increases Ten-Fold

The annual report of Lloyd's Register shows that in July, 1923, 1,831 motor vessels were in use in the United States, with a gross tonnage of 1,668,414. This compares with 297 motor vessels in use in 1914. Of the 1,831 in use in July, the sizes run: 60 over 6,000 tons; 65 between 4,000 and 6,000; 87 between 2,000 and 4,000 tons, and the remainder less than 2,000 tons.

Simple Balancing of Quantities in Highway Grading

Special Tables Afford Quick Preliminary Estimate—Reduction of Irregular Sections to Level Sections Required

By FRED. M. GARNETT

Office Engineer, State Highway Department of Georgia, Savannah, Ga.

WHETHER there should be strict adherence to the practice of balancing quantities in highway grading is a debatable question. When possible, however, this office balances quantities thereby avoiding unsightly borrow pits and waste banks along the right-of-way. The method employed has been used for more than a year on various projects in the division, and whether the cross-sections are fairly level, irregular, or very irregular the results attained are well within the limits of expectation. Indeed the method has proved to be practical, economical, and simple, within its scope of application, under widely different topographical conditions.

This method relies largely upon the use of three tables. First, a table of yardage per 100 ft. is required,

FIG. 1—PROFILE INDICATING PROCEDURE IN BALANCING QUANTITIES

with which every engineer is acquainted, and which is extensively used in almost every highway engineering office. Second, a table of areas for regular trapezoidal sections in fill is prepared, giving areas for sections from 0.1 ft. fill to 15.0 ft. fill; this table is made to conform with the standard type of roadbed adopted. Third, a similar table is prepared for regular level sections in cut. By the use of these two tables areas corresponding to any cut or fill between 0.1 ft. and 15.0 ft. can be rapidly taken off, and used in computing the yardage, together with the yardage table already mentioned. The procedure is as follows:

After having plotted the profile, decide upon the economical and advantageous limits of haul. These points are noted as shown in Fig. 1, referred to as balance points. Next endeavor to set tentative grades so that the cuts and fills will balance between these points. In Fig. 1 is shown a profile of a portion of Project S-8-108, Toombs County. It was decided to try and balance the quantities between stations 145 and 170. The tentative grade was set as shown with the object of balancing quantities.

A preliminary computation of quantities was next made between these balance points by use of the three tables described. On the preliminary computation sheets are recorded the cut or fill as the case may be for each station between the two balance points. These cuts or fills are at the center of each section and are the difference between the elevations of subgrades and the elevations of the profile. The areas corresponding to the cuts and fills are taken directly from the table

of areas, and are used in conjunction with the yardage table in computing volumes.

After having made a preliminary estimate of the quantities, they were compared and it was found that there was an excess of 1,235 cu.yd. of cut. The final grade was adjusted as shown in Fig. 1 to eliminate this excess material. Had there been a preponderance of cut over fill, the grade between stations 158 and 170 could also have been adjusted. From experience, or by means of a rough calculation, it is easy to determine how much a grade should be adjusted to balance the quantities. Since the objective balance points were selected at stations 145 and 170, by referring to the mass diagram shown in Fig. 2, some idea can be gained as to the practical working value of this method. The mass diagram shows that a balance point occurred at station 146 plus 70 instead of at station 145, and at station 169 plus 80 a balance point occurred instead of at station 170. From station 131 to station 349, a distance of 21,800 ft. on this project, no borrow or waste whatever was incurred, and economical haul was obtained.

This method of balancing quantities is not designed or intended to be absolutely accurate, since the areas

were computed for regular level sections in the preparation of the tables.

If the cross-sections are very irregular as shown in Fig. 3, they can be approximately reduced to level sections by means of a thread or triangle placed across the sections as shown by the line XY, so that the material above this line will balance the material below this line, making the necessary correction at the center, according to whether this balance line is above or below the original cut or fill shown on the preliminary computation sheet. The corrections are added to or deducted from the original values, and the volumes determined as described.

FIG. 2—MASS DIAGRAM

This method is based upon the premise that all sections are regular level sections, but such is not always the case; however, by reducing irregular sections to level sections as described, a fair working approximation can be obtained, and much of the guess can be taken out of the work.

In using this method it is not necessary to templet the cross-sections in computing the preliminary quantities; neither does the planimeter have to be used in conjunction with preliminary work. After the preliminary work is finished, the final quantities are computed and recorded on the final computations sheets, but it is not necessary to transfer the areas from the cross-

FIG. 3—LEVELING UP IRREGULAR SECTION

section sheets to the computation sheets, since only the volumes are required in computing the mass of ordinates. Much time can thus be saved, and the chances of errors minimized. The final yardage is computed from planimetered areas.

The two tables of areas can be used to good advantage in checking planimetered areas, by reducing irregular sections to level sections as heretofore described and reading the areas from the two tables. This work is only approximate, but errors of a serious nature can be readily and rapidly detected.

One of Oldest Private Water-Works Taken By City

WHEN the Proprietors of the Morris Aqueduct handed a deed of their property to the authorities of Morristown, N. J., on Dec. 15, the last of the fifteen privately owned water-works in the United States at the close of 1800 was transferred to municipal ownership. As shown by the table herewith, there were only sixteen water-works in the United States at the close of the eighteenth century and of those only the one at Winchester, Va., was municipally owned.

The transfer of the Morristown water-works comprises the entire holdings of the company, including the sources of supply and the distribution system, the latter extending into some outlying territory. The population of Morristown in 1920 was about 12,500, but it is estimated that from 18,000 to 20,000 people are supplied by the Morristown water-works. The following information regarding the purchase, together with some information regarding the early history of the plant, has been supplied to *Engineering News-Record* by Clyde Potts, civil and sanitary engineer of New York City, and mayor of Morristown:

The transfer marks the close of more than four years of negotiation with the company. On Sept. 9, 1919, the people of Morristown voted decisively to own their water-works. It was only during the past summer that negotiations were completed for the purchase of the present system. The purchase price of \$686,000 was based on an appraisal made by Willis H. Dutton, chairman of the water committee in 1920, in which pre-war prices were used. The original appraisal was \$605,000, to which \$81,000 was added for extensions and some undeveloped sources not included in Mr. Dutton's appraisal.

The Morristown water-works is one of the oldest in the United States. It was built in 1799 under a charter granted by the State of New Jersey to the Proprietors of the Morris Aqueduct, dated Nov. 16, 1799. The plant has been reconstructed a number of times since then and at the present time the plant on the whole is up-to-date.

The original plant was an aqueduct four miles in length,

including its various branches. The water supply was drawn from springs 100 ft. above the town on the Jockey Hollow Road, about a mile distant. The main supply line from the springs to the town was constructed of tile pipe, later replaced with chestnut logs, with a 2-in. bore. The original work was completed on June 20, 1799, by Pelatiah Ashley of West Springfield, Mass.

The annual gross earning of the plant is \$80,000. It is anticipated that the town will be able to pay operating and interest charges from the earnings, and apply from \$18,000 to \$20,000 to the retirement of the bonds.

The final column of the accompanying table shows the years in which the fifteen cities mentioned above as being under private ownership of water-works at the close of the eighteenth century changed to public ownership. No change was made until 1828. Between then and 1848 there were three changes. In the full decade immediately preceding the Civil War there were five more changes and in the Civil War decade itself no

WATER-WORKS IN THE UNITED STATES AT THE CLOSE OF 1800

changes whatever in ownership. From 1871 to 1896 there were six changes, thus leaving Morristown for the twenty-seven years the sole remaining town of the original fifteen under private ownership during the past twenty-seven years.

According to "The Manual of American Water-Works for 1897" there were in the United States at the close of 1896 a total of 3,196 "complete works" supplying water for both domestic and fire protection uses, of which about 53 per cent were under public ownership. Complete figures for later dates are unavailable, but of the 4,437 works listed in the McGraw Waterworks Directory for 1916 about 70 per cent were under public and 30 per cent under private ownership.

Slide Movement in Gaillard Cut

On the morning of Oct. 28 a slide involving from 250,000 to 300,000 cu.yd. of material developed on the west bank of the Panama Canal in Gaillard Cut. It was approximately 1,100 ft. long and at the point of greatest encroachment extended 150 ft. into the channel. There was ample width and depth to the east of the slide for the passage of ships of any draft, but to facilitate the work of the two dipper dredges engaged in clearing the channel, ships in transit are assembled on either side of the obstruction and held until a specified time in the afternoon when the dredges are shifted and the waiting vessels pass through. There has been no enlargement of the slide subsequent to the original movement, and it is estimated that six weeks will be required to clear the channel entirely.

Sir William Mackenzie

An Appreciation of his Greatness as a Railroad Builder and his Kindness as a Man

By Henry K. Wicksteed
Toronto, Canada

THERE LIES buried today in the churchyard of his native village, a remarkable man, justly appraised by the public press as one of the "makers of Canada"—the same public press which a few years ago was anathematizing him in connection with the Toronto railway deal as the cold-blooded head of a soulless corporation.

Sir William Mackenzie was born in 1849 in the village of Kirkfield, 88 miles northeast of Toronto, of Scotch parentage, in humble circumstances. His birthplace was in those days just as much a frontier settlement as are the outlying villages around Sudbury today or those along the North Saskatchewan farther west. Young Mackenzie grew up to manhood in this frontier settlement. He received the ordinary education of a Scotch boy, an education which evidently included the shorter catechism, for while he never in later life showed outwardly much religious feeling in the ordinary sense, he was always aware of his debts and obligations, and he learned Scotch thrift and economy. In my personal intercourse with him I found him always keen and apparently hard as nails in driving a bargain and holding the "weather gage" of a rival business man. He was almost penurious in his personal habits and tastes, but this was quite compatible with extreme generosity and kindness towards old friends of himself and his family who had been less fortunate than himself in the accumulation of this world's goods. His dislike for ostentation and display amounted to passion.

Young Mackenzie taught school for a time and engaged in mercantile business. In the early 70's one of the pioneer narrow-gage lines, the Toronto and Nipissing, pushed its way into the pineries from the neighborhood of Toronto, and it was here that he got his first experience of railroading. About the same time the "Northwest" as the central prairie belt of Canada was then called was opened up for settlement and the Canadian Pacific Ry. was initiated by the federal government. Young Mackenzie had imagination, and these signs of progress evidently fired it and stimulated him to greater things. In the 80's he went West and followed railroading almost exclusively. He did some contracting and lumbering in the mountains of British Columbia, and also on the "Short line" of the C. P. R. in Maine, and in the latter case he was one of the few contractors who carried his work through and made some money out of it.

It was at this period that he became associated with D. D. Mann—Mackenzie and Mann soon became a recognized Canadian institution. In 1890 Mackenzie became impressed with the possibilities of electrification in connection with urban railways and carried through successfully that of the Toronto system. This was his first notable success and it merely paved the way for greater enterprises. Towards the end of the century Mackenzie and Mann took up the charter of a small branch line in Western Manitoba. Instead of selling it to the C. P. R., which had now become a dominant element in the Northwest, they elected to hold and operate it themselves, and engaged D. B. Hanna, another Scotchman, as manager. To their surprise the concern paid

its way in the very first year, and this became the inspiration and the nucleus of the Canadian Northern Ry. The subsequent history is a romance which will be written some day.

The acquisition of the Manitoba, Southeastern and Ontario and Rainy River charters, and the extension of their Manitoba line to Lake Superior formed a second "Granger" line to Great Lakes navigation. There followed the expropriation of the Northern Pacific Canadian lines by the Manitoba government and their lease to the Canadian Northern, and the latter became a power in the prairie country and extended westward through Saskatchewan and into Alberta. But the end was not yet, the Canadian Northern was handicapped by being a "Granger" road pure and simple and lacked eastern connections. Negotiations with the Grand Trunk fell through. Mackenzie had conceived the idea of a transcontinental line and was bound to carry it out. The Grand Trunk wanted to buy, and failing to arrange, played on the vanity of the powers at Ottawa, and the National Transcontinental and Grand Trunk Pacific deal was the result. This was the beginning of the end and the rest is current history. Mackenzie built his through line at a fraction of the cost of the rival, but the western country was as yet too poor to support both. The final crash was hastened by the war, itself brought on by rivalry and vanity and thirst for power.

Mackenzie's personal vanity was absurdly small. His desire was for achievement. Money was merely a means to an end. Quick and hot-tempered, he was always amenable to argument and reason, and some of the pleasantest hours of my life, possibly of his own, have been spent in poring over maps and plans with him, and formulating development schemes. How much of his success was due to personal magnetism, how much to the spirit of romance and adventure which hung over the whole project, is hard to say, but he had in a rare degree the gift of putting the right man in the right place, and implanting and retaining loyalty in his subordinates. The loyalty was not only to himself and his partner and the enterprise, but it bound the heads of the different departments together as actual friends. Never was there an organization with fewer internal jealousies and rivalries. Unquestionably much of his success is due to this. He heartily appreciated the man who as a matter of principle could fight him with his own weapons.

The Toronto mayor who drove a hard bargain with him over the Toronto Ry. franchise became a warm friend and later manager of the system. How much, again, of his success was due to his partner, D. D. Mann, of different temperament, but with profound knowledge of railway construction and of men is hard to judge. And last, but not least, how much was due to the gracious lady, his wife, a native of his own village, who rose with him, and was for years the chateleine at "Benvenuto," his Toronto home, and a recognized society leader in the truest sense!

Dravo Contracting Co. Built South St. Bridge

The statement in *Engineering News-Record*, Nov. 22, 1923, p. 861, regarding the opening of the city-built bascule bridge over the Schuylkill River in Philadelphia at South Street, should have named the Dravo Contracting Co., Pittsburgh, as contractor, instead of the American Bridge Co. The Dravo Contracting Co. had the entire contract, but sublet some of the construction to the American Bridge Co.

Concrete Aggregate Produced From Local Deposit

High Cost of Imported Stone and Sand, and Uncertainty of Transportation, Lead Contractor to Screen Gravel on Job—Cubic Yard Cost Far Below Cost from Outside Sources

By J. ARTHUR GARROD
General Superintendent, Aberthaw Construction Co.,
Boston, Mass.

IN APRIL, 1922, the Aberthaw Construction Co., of Boston, Mass., was awarded a contract at Northbridge in Southern Massachusetts, for constructing three buildings for the same owner requiring aggregates for some 11,000 cu.yd. of reinforced concrete. The original estimate contemplated the use of 1½-in. crushed stone for coarse aggregate, with a reduction in price if similar sized gravel was substituted. It was decided by architects to accept the proposal for the use of gravel. Crushed stone, as specified, would have cost \$2.35 per ton f.o.b. cars near the main part of operations. Gravel screenings were offered at \$2 per ton on cars, and would have cost still more if the architects' requirements to use all 1½-in. stone had been strictly enforced. Good concrete sand was offered at \$1.75 per ton on cars at the job.

When plant requirements were surveyed it was found that all the side-tracks in the immediate vicinity of the job would be required for the handling of cement, so that unloading space for aggregate, and machinery for unloading, if provided, would have to have been at some distance from the sites of the four mixers used on the widely separated buildings. Railroad conditions, although unsatisfactory at the time work was started, showed signs of becoming more so; so that the use of local materials, even at the same price, was most desirable.

Preliminary Examination—An examination of all developed and some undeveloped deposits within a three-mile radius showed several possible sources of supply, two pits proving superior to all others. Both of these contained excellently graded material. The pebbles in both pits had an adhering coating of clay, a coating which was not present in harmful quantity in the sand. This material could be purchased at 10c. per cubic yard, bank measurement, all overburden removed being deposited on the premises and only the quantity actually taken away to be paid for. One of the two deposits had been worked intermittently for years; the other deposit had been worked on a previous occasion but a large knoll was practically unexplored. Eight test holes showed excellent gravel in sufficient quantity but with two to three feet of overburden. The first-mentioned deposit was finally decided upon as it was located nearer to a good road and within 1,500 ft. of the Blackstone River.

A trucking concern interested us in a method of screening with the aid of portable gasoline-driven belt conveyors. They guaranteed to supply coarse aggregate at \$2.50 per yard, and fine aggregate at \$1.50 per yard delivered at the site, two miles from the pit. A week's trial showed we could not rely upon their method: the sizing of the coarse aggregate was not acceptable; oversize stones cluttered the pit; the adhering coating of clay was not loosened from the stones; the usual controversy commenced regarding the

size of loads, so the Aberthaw company decided to erect a plant and prepare the aggregate by its own forces.

A sample of the sand showed a tensile strength of 110 per cent of Ottawa standard sand, so the architects decided that the finer material was suitable without washing. Screen analyses of the pebbles showed them to be well graded, and examination showed them to be of more than average hardness. As some 10 per cent were larger than was permissible in the concrete, a crusher was needed. The architects required that the coarse aggregate be washed free from the adhering coating of clay.

The outlay for a special washing and sizing plant for treating the material would have been large and would not have been justified on account of the temporary nature of the installation. The Aberthaw company then decided to install used crusher, elevators, screen and pump stored at the time in their Boston yard. The electric service company was ready, for a small installation charge, to provide supplementary transformer facilities and to supply power at the current authorized rates.

Design of Plant—The job force, under the writer's direction, proceeded to design the plant and bins and to obtain the most suitable equipment available at Aberthaw's yard.

The rotary screen, erected lengthwise of the bins, was 32 ft. in diameter and 16 ft. long; the upper 7 ft. of this screen was perforated with ½-in. holes, the remainder with 1½-in. holes.

A bin and gate were used at first for feeding the boot of the elevator but this was found unnecessary as an 8-in. x 12-in. timbered opening at the floor elevation of the pit gave a fairly regular supply of material and enabled the horse scrapers to be dumped directly over it. The excavated gravel was raised with a single chain bucket-elevator having 15-in. buckets spaced 12 in. c. to c. on the chain. The elevator fed the gravel through a chute 3 ft. long, at a 45-deg. inclination, to the head of the screen. The total height between the bottom-shaft and head-shaft of the elevator was 40 ft. The sand was screened dry and the 40 per cent sand determination, made at the beginning, remained fairly constant throughout the operation. The bin was partitioned accordingly. Oversize pebbles or tailings remaining on the screen were conveyed to the crusher through metal-lined gravity chutes. A 10-hp. motor supplied all necessary power for this screening and elevating outfit.

The jaw-crusher had a 12-in. x 20-in. opening and a rated capacity of 12 tons per hour. It was set on a concrete foundation at right angles to the direction of the screen. The product of the crusher was raised by a bucket-elevator similar to the one which raised the gravel. Crushed pebbles and stonedust were dumped from the head of the elevator into a short chute at right angles to the long chute which fed the gravel

from the main elevator to the screen. The clean angular stones and stonedust from the crusher, thus introduced into the gravel, assisted materially in both dry and wet screening operations. A 25-hp. motor, belted directly to the crusher, supplied power to both crusher and elevator. At no time was this crushing outfit used to capacity but both fine and coarse aggregates were improved by the addition of the material resulting therefrom.

To remove adhering clay from the stone, streams of water were played upon the coarse aggregate from a heavy 3-in. pipe, 16 ft. long, which was introduced at the head end of the rotary screen. The portion of this pipe which corresponded with the $1\frac{1}{2}$ -in. holes in the screen was perforated with a double row of $\frac{1}{8}$ -in. holes spaced $1\frac{1}{4}$ in., the aggregate area of the openings being slightly larger than the pipe diameter. The pipe was turned so as to direct the water against the sector of the screen where gravel would lie when the screen was rotating. The extreme end of the pipe was blanked off and formed a bearing which

with wires $\frac{1}{8}$ in. apart, this mesh being arranged with a sharp slope to either side of the trough so that the muddy water would pass out comparatively free from sand grains. This modification enabled us to produce a clean coarse aggregate under normal running conditions. Some clay from the water which had been used for washing was still accumulated in the coarse stone remaining in the bin when bin-gates were operated normally. During repairs, when it was necessary to empty the bins, this clay was removed by thoroughly washing with a hose and nozzle connected with the wash-water supply.

The bin was 20 ft. long, 12 ft. wide and 12 ft. deep. It was built of second-hand yellow pine timbers and local hardwood plank. It was arranged so that trucks could back up under the side opposite the crusher, leaving the head end free for the screen, and the lower end free for handling the tailings. One bottom circular bin-gate and one angle circular bin-gate were used in each of the two compartments. Practically no spreading was necessary in the truck as the truck moved slightly ahead when partially filled, receiving the load

PLAN AND ELEVATIONS OF ABERTHAW GRAVEL SCREENING PLANT AT NORTHBIDGE, MASS.

carried the pipe on the revolving shaft which supported the back end of the screen. Some of the perforations were subsequently plugged so that the largest streams of water were concentrated near the middle of the screen.

Water for washing purposes was pumped from the Blackstone River about a quarter of a mile away, the water being handled by a large-periphery single-stage centrifugal pump adapted for high lifts. A 10-hp. motor was belted to this pump and gave ample power. The total head, including the usual allowances for friction and bends, was 45 ft. The water was conveyed to the gravel plant through a 3-in. steel pipe, purchased second-hand. As the installation was temporary and not designed to operate in freezing weather the pipe was laid over the ground. The waste water from the washing operation was designed to fall out through a grating towards the back of the coarse aggregate bin and run through a surface ditch to an abandoned canal which formed an excellent sedimentation basin. The water which reached the river contained no mud or suspended matter.

Plant Operation—Difficulty in operation was at first experienced as the screened gravel in the bins became contaminated by the dirty water from the washing. This was later obviated to a large extent by the introduction, near the center of the bin, and immediately under the screen, of a trough formed of a 15-in. structural steel channel covered with a stout galvanized mesh

evenly. The truck drivers left their cabs to operate the bin-gates but without descending to the ground. The ground grade was arranged to slope away from the bins. The floor of the gravel pit was above the grade of the highway, so the trucks were not delayed in loading or getting away.

It was found that one man could attend the entire plant and take care of the tailings, except when the material in the bank was wet following a rainstorm. The plant was placed against the available faces in the gravel pit so that some excavation was necessary to make room for the crusher and the bottom of the gravel screen. A 15-ft. depth of face was available when operations started. From 12 in. to 18 in. of loam and other overburden had been removed and care was taken that the material fed to the plant should include due proportions of the various strata. At first the feeding was done by hand-shoveling from the immediate vicinity of the elevator boot. After a few days this was supplemented by a pair of horses and a drag scraper, a method of excavation used exclusively thereafter. Near the end of the operating period the haul to the boot averaged 250 ft. Five was the maximum number of teams and scrapers used at any one time. As the haul became greater wheel scrapers were tried, also a much advertised kerosene-driven tractor, without and with crawling traction. The soft underlying sand made the hauling too heavy for wheel scrapers and did not afford

proper traction to the tractor, so these methods were not adopted. Some form of dragline excavator was carefully considered but on account of the wide angle it would have been necessary to cover this method was not considered economical.

Production and Handling—A larger amount of sand was produced by the screening plant than was needed for concrete. To handle this surplus an occasional truckload was removed from the bin and deposited on the floor of the gravel pit near the road. To make the maximum use of this sand and to facilitate handling, two 16-in. x 24-ft. portable electric-driven belt conveyors, with low belt-cleats, were purchased. One of these had a device for screening the surplus concrete sand into peastone or torpedo sand for granolithic finish, and finer material for brick mortar. These conveyors loaded trucks from storage piles economically but the screening device was of little use as a small amount of moisture in the sand prevented its further separation. Most successful operation was

cu.yd. remained in the gravel pit as a surplus when concreting was completed. All surplus fine aggregate was trucked to the job as backfill and is included in the 14,309 cu.yd. reported.

The maximum storage around the mixers which could be used economically would care for one day's run only, so that during the active period of the job it was found necessary to install incandescent and flood lights at the gravel pit and to run during the night as well as during daylight hours to provide sufficient aggregate for the daily scheduled runs of concreting. The labor cost of night operation averaged one-third higher, when work was running well, than during the daytime; and occasional breakdowns, when the needed help to make unusual repairs was not immediately available, still further increased costs.

The plant was in operation June 7 and work of dismantling was started October 17, a period of 18 weeks. Allowing for Sundays and wet weather, an average of 143 cu.yd. of both coarse and fine aggregate was pro-

TABLE—ESTIMATED CONTRACT COST OF GRAVEL AND ACTUAL COST WITH SCREENING PLANT ON JOB

Performance	Estimated Cost	Actual Cost	Actual Unit Cost per Yard of Material Del'd at Mixers	Saving	Overrun	Remarks
1. Labor stripping bank, 1,100 cu.yds.	\$1,200	\$529	\$.037	\$671		Overburden piled on premises.
2. Labor on plant unloading, erection, maintenance, dismantling and loading.	1,825	2,196	.154		\$371	Includes lubrication, repairs and upkeep.
3. Labor of operation, including foreman, teams and men loading and handling, 14,309 cu.yds. of coarse and fine aggregate.	6,609	10,663	.745		4,054	Estimated 13,217 cu.yds. @ 50c.
4. Trucking aggregates from pit to mixers, 14,309 cu.yds.	7,930	8,222	.575		292	Estimated 13,217 cu.yds. @ 60c.
5. Proportion of overhead at main job office.		570	.040		570	Includes watchman Sundays and holidays.
6. Electric power and installation, including wiring for motors and lights.	800	1,195	.084		395	Amount of salvage received allowed for.
7. Plant rental.	2,600	2,235	.156	365		Crusher, screens, elevators, pumps, repair parts and renewals on rented equipment.
8. Lumber for bins, bolts, nails, etc.	500	456	.032	44		Amount of salvage received allowed for.
9. Pipe for wash water supply (2nd hand)	200	206	.014		6	Amount of salvage received allowed for.
10. Two portable belt conveyors.		918	.064		918	Includes freight from factory and allowance received for salvage.
11. Freight, express and trucking on equipment.	250	303	.021		53	From Boston and return.
12. Sundries, including hand tools, horse scrapers, bin-gates, grease, oil, waste, etc.	50	664	.046		614	Amount of salvage received allowed for
13. Paid to owner of pit for material removed.	860	1,245	.087		385	12,451 cu. yd. bank measurement.
	\$22,824	\$29,402	\$2.055	\$1,080	\$7,658	
Overrun.	6,578			6,578		
	\$29,402	\$29,402		\$7,658	\$7,658	

attained during long spells of dry weather. These conveyors were readily moved around within the pit but it is extremely doubtful whether the results obtained justified the expenditure made for their purchase and upkeep.

The two-mile haul from the pit to the mixers was accomplished by 3½-ton dump trucks hauling about 4 cu.yd. per trip. These were hired at \$2.50 per hour including driver, fuel, oil, etc. No serious mechanical difficulties attended the use of these trucks and the road, although hilly, remained in fair condition throughout the season. Some scraping with a road drag had to be done on a stretch of unimproved highway near the pit during spells of wet weather. No accident to persons or property attended the operation of the trucks although the route traversed was through the principal business street of the town.

The overburden excavated was 1,100 cu.yd., which was left in the gravel pit; 12,451 cu.yd. of material were measured in the bank and paid for; and 272 cu.yd. of prepared material were sold at the gravel plant and trucked by others. The cost of preparing this material and the price received for it have been excluded from the figures tabulated. Of coarse aggregate 244

duced daily, including about 30 nights when gravel was produced and transported.

During wet weather the sand would not separate in the dry screen and some few loads had to be re-screened by hand to enable proportioning to be consistently accomplished at mixers.

The quality of the material was maintained throughout; 1:3 briquettes made with the sand averaged well over 100 per cent of Ottawa standard. An occasional batch of 1:2:4 cylinders was made, which, when crushed at 28 days, gave average strengths of over 3,000 lb. per square inch compared with the average of under 1,900 lb. obtained from aggregates from the same pit before the plant was operating.

The estimated and actual costs are tabulated above.

Average Cubic Yard Cost—From the table of comparative costs it will be noted that the average cost of coarse and fine aggregate delivered by trucks at the mixers was \$2.055 per cubic yard. No direct comparison can be made with other sources of supply as no concern or concerns were found who could supply gravel screenings as required. The one concern which did bid, was tried and proved unsatisfactory. Acceptable crushed stone could have been purchased for \$3.13

per cubic yard f.o.b. cars, plus an estimated cost of 50c. for unloading and trucking to mixers. Freight conditions during the construction period were such as would have made it hazardous to rely upon obtaining aggregates by rail, and the absence of unloading facilities would have made it extremely difficult to receive the material by cars even though car service had been satisfactory.

Thus assuming that crushed stone at the above price and sand by cars at \$2.33 per cubic yard could have been made available, and the unloading from cars and trucking to mixers could be accomplished at 50c. per yard, the average price at the mixer would have been \$3.36 per yard against the actual cost recorded—\$2.055 per yard. Similarly, assuming that gravel screenings could have been obtained at \$2.66 per yard f.o.b. cars with 50c. for unloading and trucking, then the average price of screenings and sand would have been \$3.16 against the \$2.055 actually obtained.

Alum, an Aid in the Filtration of Activated Sludge

Sanitary District of Chicago Finds Alum Success at Three Plants with Advantages Over Use of Acid

UNIFORM success in the use of aluminum sulphate in the pretreatment of activated sludge for pressing has been attained at three sewage treatment plants of the Sanitary District of Chicago. Alum is found preferable to acid as an aid to filtration since it is safer to handle, it decreases time of filtration, it is as cheap, gives a clean filtrate and it is not necessary to control the amount within narrow limits. F. W. Mohlman, chief chemist, in a paper presented recently to the American Chemical Society at Milwaukee, described experiences of the past year with alum, mostly with plants of full-size working scale, at Des Plaines, Calumet and Argo. An abstract of his paper follows:

Des Plaines Works—Approximately 3,000 lb. of dry activated sludge is produced daily at the Des Plaines works. As removed from the aeration tanks the moisture content averages 98 per cent, although it frequently is as low as 97 per cent. Sludge is removed for pretreatment from the Dorr thickeners daily and stored in rectangular tanks containing filtercloths tile aerators. From these storage tanks the sludge is pumped directly to the filters.

When the press house was put in operation, in September, 1922, two types of presses were available. The first was a 120-plate Simplex press, a typical recessed-plate filter press with a special type of grooved recess. A perforated sheet-metal plate was riveted over the grooves on which the filter cloth rested. The plates were center-feed. The thickness of the cakes was 1 in., and the filtering area was 1,815 sq.ft. Pressure could be built up to 125 lb. per square inch. The Worthington platen press, similar to the one used at Milwaukee in 1918, held eighteen bags, each 5 x 8 ft. in area, supported between perforated platens. The filtering area was 1,440 sq.ft.

The first few pressings were made with untreated sludge. The bags soon clogged, and slimy cakes were produced, even with a long pressing of from 7 to 8 hours. It became increasingly difficult to handle the sludge produced.

Acid was used for a number of pressings, and as far as practicable the pH was adjusted to the optimum value, approximately 3.5 as shown by laboratory tests with Buchner funnels. Results were very unsatisfactory, with wet slimy cakes and dirty bags. It was necessary to press 24 hours per day, with a chemist present only during the day shift, consequently perfect adjustment of the acidity could not be obtained.

A marked improvement in filtration was noted immediately on the use of alum. The cakes were dryer, the time of filtration was shortened and the bags were cleaner. The use of alum was so satisfactory that it was adopted as routine procedure in the pretreatment of sludge.

The comparison of the relative efficiency of acid and alum for pretreatment, shown in the table, was obtained by filtration of 250 c.c. of treated sludge through a battery of Buchner funnels, using a sludge with 99.06 per cent water.

TABLE—RELATIVE EFFICIENCIES OF ACID AND ALUM FOR PRE-TREATMENT OF ACTIVATED SLUDGE

Sulphuric Acid—66 Deg. Ré				Filter Alum			
c.c. per Gal.		Time of Filtration Min. and Sec.	pH	lb. per 1,000 Gal.		Time of Filtration Min. and Sec.	pH
0	7:30	7 1	0	0	8:00	7 1	
1	10:15	6 2	3	3	2:00	6 7	
2	9:30	5 3	6	6	1:50	6 4	
3	6:00	4 3	9	9	1:40	5 2	
4	5:00	3 2	12	12	1:30	6 0	
5	4:00	2 5	15	15	1:15	5 8	

These results have been verified a number of times, and show facts which indicate why alum has proved so much more satisfactory than acid. An insufficient amount of acid, or a drift back to a pH between 5 and 6 may actually cause an increase in the time required for filtration. On the other hand the addition of even small amounts of alum produces a sharp decrease in time of filtration, with little tendency toward deflocculation, and at no time an actual increase in time of filtration. The curve shows no "humps," and no sharply defined iso-electric point. Similar results have been noted by Van der Meulen and Smith in experiments on the use of alum for coagulating Imhoff sludge.

Laboratory tests, proved by months of practical operation, have shown that the sludge may be too concentrated for effective use of alum. These observations have resulted in the following procedure for the pretreatment of the sludge: The sludge is drawn into the storage tank, where its moisture content is determined approximately by means of a special hydrometer which has been calibrated by many tests on sludges of various moisture contents. If the apparent moisture content is below 98.5 per cent, effluent or city water is added to bring the moisture up to that point. Alum is then added, never more than 10 lb. per 1,000 gal. If possible the sludge is used up within 6 hours; if it has to stand 24 hours more alum is added.

The pH is usually decreased to 5.8 to 6.0, at which point practically all the alum is precipitated as $Al(OH)_3$. It will be noted that the function of the alum is thus as a coagulant used in water filtration, and not for its salt effect, after the iso-electric point has been obtained by the use of acid. Much lower amounts are required if alum is used as outlined than if acid and alum are used together.

The amount of alum left in the sludge as a diluent of the valuable nitrogenous material is absolutely negligible. At the rate of 10 lb. per 1,000 gal. of 98.5 per cent sludge, only about 30 lb. or 1.5 per cent of Al_2O_3 will be added to a ton of dried sludge.

Alum has been used as described above since October, 1922, with uniform success. We encountered no so-called "winter sludge"; pressing and pretreatment were for practical purposes just as satisfactory in January and February as in July and August. We did, however, encounter a period of difficulty in April, 1923, when we attempted to cut the air in the aeration tanks to the minimum amount capable of giving an effluent that would not decolorize methylene blue in less than 8 or 10 days. We gradually reduced the air to as low as 0.66 cu.ft. per gallon, but as we cut the air the nitrates in the effluent were reduced from 7 or 8 p.p.m. down to 1 or 2 p.p.m. The effluent was still clear, but stabilities began to drop off. The main difficulty was noted in the filtration of the sludge. Although the same pretreatment was continued, in fact the alum dosage was increased, slimy cakes were obtained and filter cloths clogged rapidly. The air was soon increased to 1.2 cu.ft. per gallon and the nitrate built up to 5 to 10 p.p.m. Coincidentally the sludge began to press more easily, and soon was back to its former satisfactory condition.

The present trend of development of the activated-sludge process seems to be in the direction of decreased aeration and minimum nitrification. Numerous mechanical and biological schemes are proposed which require less power than that required by aeration with compressed air, but generally no nitrification is obtained. The writer believes that thorough activation, as evidenced by formation of 5 p.p.m. or more of nitrate nitrogen, is essential for the production of a sludge that will filter easily.

Calumet Works—The Calumet works include two activated-sludge units, each with a capacity of 1.75 m.g.d. Sludge was built up and ready for pressing in June, 1923. An Oliver filter has been installed and has been filtering all sludge produced. This filter is 11½ ft. in diameter and 14 ft. long and is covered with 495 sq.ft. of filter cloth. It has not been possible to run for more than 7 or 8 hours continuously with this filter as the sewage is quite dilute and the sludge accumulates slowly. As at the Des Plaines works it was found that untreated sludge would not filter satisfactorily. Alum was used for preparation of the sludge, but it was found desirable to add more alum, up to 14 lb. per 1,000 gal. A number of tests with Buchner funnels indicates much more rapid filtration with alum treatment than with acidification. The filter has worked satisfactorily during the short time it has been operated. The average rate of filtration has been approximately 0.011 lb. of dry sludge per square foot of filtering surface per minute. This high rate of filtration, combined with the fact that filtration is continuous and cleanly, has indicated that this type of filter is preferable to the pressure filters at Des Plaines.

Corn Products Testing Station—An unusual type of activated sludge has been produced at the testing station treating the wastes from the Corn Products Refining Co., at Argo. This sludge is usually very light and voluminous, frequently containing over 99 per cent water. It contains more than 75 per cent organic matter on the dry basis, and from 6.5 to 7.5 per cent nitrogen. The problem of pressing this sludge is unusually difficult because of its watery nature and the rapid changes in its character due to biological conditions.

Two filters have been used for pressing this sludge, a recessed-plate filter press and a small American continuous filter. The latter is a rotating leaf suction filter containing 20 sq.ft. of filtering surface. In principle it is similar to the Oliver filter. Many substances have been used for pretreatment of the sludge before filtration. It was frequently found impossible in the winter of 1921-22 to produce a cake in the filter press, no matter what was the pretreatment.

The American filter has offered more hope. Sludge has been pressed both hot and cold many times, using, as filter aids, sulphuric acid, alum, di-calcium phosphate, spent bone ash, sulphur dioxide and filter-cel.

Conclusions—General conclusions are as follows:

1. By suitable pretreatment of the sludge it should be possible at all times to produce a cake with a type of suction filter similar to the American filter.

2. A very dilute sludge (99.5 per cent water) or one not well-activated cannot be pretreated with any of the above substances, including heating to 150 deg. F., so as to give a high rate of filtration (that is, a rate greater than 0.08 lb. per square foot per minute). A well-activated sludge with a moisture content of 98.5 or 99.0 per cent can be treated with either alum or acid, with or without heating, and will give a satisfactory cake with a high rate of filtration. The moisture content without heat is usually about 85 per cent, with heat from 80 to 82 per cent. Heating apparently does not materially increase the rate of filtration. Alum treatment is generally more effective than acidification.

3. Phosphates, bone ash, filter-cel and sulphur dioxide are of little value.

4. The ratio of time of pick-up to time of drying is fixed. It would be desirable to be able to vary the ratio, that is, to shorten the time of pick-up with a heavy sludge and to lengthen it with a dilute sludge. Control of the degree of vacuum or blanking off of one or more sectors are unsatisfactory methods for accomplishing such variations.

Flood Flows or Maximum Runoffs of Montana Streams

Tabular Data and Curves for Streams East of Divide, West of Divide and on Prairies, Based on Recorded Runoffs

By GEORGE HENRY ELLIS

Hydrographer, Office of State Engineer, Helena, Mont.

IN DETERMINING the required capacity of the waterway under a bridge, a highway or railway culvert, or the spillway of a dam, the best method is to be there when the greatest flood occurs and measure the discharge. If that has not been done, perhaps the next best method is to find some marks left by the highest flood, and make an estimate of quantities based on measurements of cross-section and slope. If this method, in turn, is impractical or uncertain, the drainage area

tributary to the stream at the proposed structure may be measured and compared with some similar area for which the maximum flood is known. Data for use in the latter method on streams in Western United States, and in New York State, have recently been presented in these columns, and similar data for Montana are given herewith. (See *Engineering News-Record*, July 3, 1919, p. 28, article by John T. Whistler, and Nov. 4, 1920, p. 879, article by E. H. Sargent.)

In a country so varied as to climate and topography as Montana, considerable judgment must be used in basing estimates on data of this sort. Even after the data have been classified as to mountain streams (1) East, and (2) West of the Divide, and (3) Prairie streams (see table and diagrams), there are still no two drainage areas just alike as to exposure and forestation. Many streams in Montana are so thoroughly used for irrigation that even the flood flow is affected thereby; for example, Beaverhead River at Barratts did not have a greater discharge than 1.27 sec.-ft. per sq.m. during the sixteen years, 1907-1922. Many Montana streams have not experienced their maximum flood during the period for which records have been obtained, and perhaps the Beaverhead is one of these.

The data are from published records. Some represent absolute maximum, as obtained from an automatic water-stage recorder, and others are maximum reading of a gage which was read one or more times per day.

MAXIMUM FLOOD DISCHARGES OF MONTANA STREAMS EAST AND WEST OF DIVIDE AND ON PRAIRIES

Federal Land Reclamation: A National Problem

9. The Future of Federal Reclamation

By HON. ADDISON T. SMITH

Chairman, Committee on Irrigation of Arid Lands, House of Representatives, U. S. Congress

The Ninth and Last of a Series of Articles on History and Performance of the Great Government Adventure in Irrigation of the Arid lands of the West

THE 68TH CONGRESS, which has just assembled, has before it innumerable problems of national and international importance, many of which are of great interest to engineers as such, as well as from the standpoint of good citizenship. Among these questions, there is perhaps none more vitally important, as it relates to the stability of government and of business institutions, than that of the national policy of land reclamation and settlement. From the earliest times the land question has been recognized as fundamental in the stability of all government. In fact, one of the most difficult questions and one which threatened the existence of the nation as a whole was that growing out of the ownership and use of the vast tracts of land west of the original colonies; when the title to these lands was finally confirmed in the United States, then and not until then was the stability of the Union assured.

The necessity of using these public lands for homes for citizens was early appreciated, but the ways of assuring such best use were not finally agreed upon until the passage of the homestead act, which in effect dedicated to home-making the greater part of the public lands of the country. The growth of the United States in population, industry and in everything that makes for good citizenship has been closely connected with the utilization of the vast extent of lands which could be employed in the creation of the small self-supporting farm homes—small in distinction from the great estates or ranches of other countries but large enough to absorb the available labor of the owner and his family.

Reclamation to Develop Homes—The fact that these public lands, suitable for home-making, had practically disappeared by the beginning of this century led Theodore Roosevelt and his associates to urge that the benefits of the Homestead Act be extended, not by annexing lands belonging to other nations but by internal expansion, by removing obstacles to the cultivation of lands which were then lying idle because of lack of water. In his first message to Congress, December,

1901, Roosevelt urged that the public lands of the arid region be reclaimed so that homesteading might continue. Under the stimulus of his personal interest in the matter and with the active efforts of many notable statesmen the Reclamation Act finally became a law, being signed by President Roosevelt on June 17 (Bunker Hill Day), 1902.

Two decades and more have elapsed since that time. The vacant public lands so far as these may be irrigated or reclaimed have practically all disappeared. Although about 190,000,000 acres of vacant public lands remain on the tract books of the Land Office, practically all of these consist of rejected areas—of mountains, plateaus or rock-strewn valleys, and lands where the soil is too thin for cultivation. Every valley in the arid region has been explored, every piece of land which under any conceivable plan may ultimately be utilized is gone, so far as government reclamation is concerned.

The extraordinary and unlooked-for success of the Reclamation Act has resulted in a great stimulus of enterprise in the arid region as a whole, and to an extent such as to force land prices so high, as

compared with recent crop values, as to render further reclamation plans a matter for serious consideration from the financial or economic standpoint. Many of the projects now proposed may cost more than the productive value of the land.

Is More Reclamation Needed?—It is not to be inferred that the West is completely developed. On the contrary, we are at the beginning of development, but we must go at it in some other way than has been practiced in the past. This is shown by the many applications for relief from payment of the installments due the government. This is in spite of the fact that the conditions for such payment for water for the reclaimed land have been made, by act of Congress, more lenient than in any other part of the world or by any other country or organization. Last year 2,000 settlers applied for relief or extension of time of payment, and this year over 4,500 are urging

Congressman Addison T. Smith on Future Reclamation Problems

Many of the projects now proposed may cost more than the productive value of the land.

We are at the beginning of development, but we must go at it in some other way than has been practiced in the past.

A self-supporting home established in the East is as important to the nation as one in the West.

The existence of public lands should not be made the prerequisite for the continuation of the national policy of home-making. On the contrary, this policy should be adapted to present conditions of land ownership.

The formation of reclamation districts under state law is one of the large steps in advance. We must go back to the original conception, that if the government initiates the work and puts it on its feet there must be some organization or district acting under state law which must take up the petty details of dealing with the individuals.

The federal government is furnishing all the money, doing all the work, is being criticized because it does not enter into more details, while the state is doing little or nothing in the way of solving the problems of its citizens on the reclaimed lands.

some concession. Many of these claims are doubtless meritorious, but the fact that so many are making application indicates that there must be some change in present methods.

It should not be assumed that the West, which has contained such vast areas of public land, is the only undeveloped portion of the United States. The country as a whole, as concerns its continued growth and prosperity, cannot confine its efforts to any one section. A self-supporting home established in the East is as important to the nation as one in the West. It is the contented and prosperous home which should be considered, not the particular locality of that home.

This important consideration that the nation is concerned, not with the reclamation of public land because it is public land, but with the ultimate object of home-making gives a broad view of the situation. It forces us to consider the opportunities offered in every part of the country. For many years the people of the South have been insistent that so far as national and business stability are concerned it is the unused land of the South which should have early consideration. They have claimed that with the rapid development of the West, the South now presents more opportunities. There are no public lands remaining in the South. The existence of public lands should not be made the prerequisite for the continuation of the national policy of home-making. On the contrary, this policy should be adapted to present conditions of land ownership and be so modified as to encourage the settlement of vast tracts of land suitable for homemaking.

Opportunities In the South—There is no doubt but that the success of reclamation in the West has stimulated other parts of the country to demand that equal consideration be given to their claims. It is a matter of history that when the Reclamation Act was under consideration the South voted to help the West and with the understanding that, if the time should come that the South was in a position to need similar legislation, the western men would come to its aid. The time has now arrived when the people of the South are demanding such consideration and are pointing to the fact that if the ultimate object of the Reclamation Act is the making of homes, then, under present conditions, homes can be made in the South as well as in the West.

To put it in another way, the success of national reclamation in the arid region has stimulated interest and enthusiasm in the underlying ideals of home-making, and if the West is to continue with federal assistance it must share this with other parts of the country. It can no longer stand alone or claim the unique distinction of having public land to be reclaimed in any considerable tracts.

This claim for general consideration is by no means new. Congress has already recognized that something should be done; in 1918 it appropriated \$100,000 for a study of the unused lands in every state. The report, printed in 1919, illustrates the fact that there are lands available in every section of the country, many of which may be utilized as need arises. It is true that these lands are in private ownership, individual or corporate, but they can be obtained on terms not much more onerous than those attached to public lands. The owners of many of these tracts, seeing the hopelessness of financial gain in the reclamation and settlement of these lands, have offered to turn over these areas to bona fide

settlers at rates which may be approved by competent authority as being fair.

It is possible to conceive of a land reclamation and settlement district, organized under the state law, embracing suitable lands and conducted in such way as to give reasonable assurance to home-seekers that they will have a square deal. It is also possible to conceive that the financing of such districts may be done under federal auspices in such way as will ultimately recover the investment, although the interest may be lost to the government during the years of pioneering. Compensation for this loss of interest is more than made up by the fact of the ultimate settlement of the land, and the making of self-supporting homes. It is recognized that, in every undertaking of this kind, some aid must be given; the most effective way is through this forfeiting of interest on the investment during these early stages.

Improvement of Existing Laws—The Reclamation Law as it now stands is applicable only to lands in the sixteen arid or semi-arid western states, Kansas to California, Montana to Arizona. It has been amended from time to time in certain details, particularly those having to do with the repayment of the amount owed to the government on account of the capital investment in irrigation and drainage works. The result is that the law as a whole is more or less of a patchwork; it is somewhat inconsistent in its details and requires for effective application many fine-drawn distinctions or inferences which should be covered by explicit statement of principles. In short, the methods of administration forced by the necessities of the case are not embodied in the law but are permissible by inferences drawn from apparent intent of the act, rather than from direct authorization.

This latitude of the reclamation law was very desirable and even essential twenty years ago, when conditions were almost unknown, but now that federal reclamation has become an established fact, it is the part of wisdom for Congress to recognize the larger needs and to place responsibilities more definitely than in the past.

Reclamation Districts—The formation of reclamation districts under stated law is one of the large steps in the carrying out of the objects of the Reclamation Act. These districts should be encouraged or even compelled to take a larger responsibility in the administration of affairs, not leaving the land owners and their tenants to shift the burdens of operation and maintenance to the shoulders of Uncle Sam. The Reclamation Act in its very essence requires that large responsibility be assumed by the federal department or bureau having the matter in charge, but the duties have been greatly increased by this strongly marked tendency to force good-natured Uncle Sam to carry the burden longer and to a larger extent than was contemplated originally.

Under the Act of 1902, it was assumed that payments would be made without interest during the pioneer period of ten years, and that before this time had elapsed the local people would have assumed full responsibility and control. Congress extended the time to twenty years, but made no requirements such as to facilitate the government's laying down the burden. Recently, a provision was inserted in one of the Appropriation Acts which may require the government, in connection with the Milk River project, in Montana, to keep control and practically peddle out water for fifty

years. It is thus forced to interfere in the local affairs of water distribution to small communities, a condition which tends toward continued misunderstanding and exasperation. We must get over this and go back more nearly to the original conception, that if the government initiates the work and puts it on its feet there must be some organization or district acting under state law which must take up the petty details of dealing with the individuals.

Extension of Time—In connection with the operation of the Reclamation Act there is no one thing which has taken up so much time of Congress and in its committees and has led to such exasperation on the part of its members as the steadily increasing demand for extension of time of payment. At the end of the first ten years, Congress concluded that a ten-year period for payment of the capital invested in the water which made the farm available was too short, even though this payment was made without interest. After considerable discussion it was concluded to grant *terms so easy that under no possible condition could any landowner fail to make good*; that is to say, to make the installments on the capital invested less than the ordinary payment of interest.

For example, the government may have invested \$80 per acre in the reclamation of land. This land was given away originally under condition of settlement. The man getting this piece of land was required to pay this \$80 for the water in installments without interest, extending over a period of twenty years. To put it in another way, if the landowner paid 5 per cent a year for twenty years, he could have the water for nothing. More than this, to cover the pioneer period, it was provided that for the first four years the landowner need pay only 2 per cent installments, then for the fifth and sixth years only 4 per cent installments, and for the remaining fourteen years 6 per cent, all of these without interest on the deferred amount. Here were terms far easier than those offered by any country or community and Congress gave a sigh of relief that the whole thing was settled and for all time. Many members thought this too easy, and urged that at least a small interest charge should be demanded, and conditions after the first ten years made comparable to those of the Federal Farm Loan banks.

Now, however, after a few years of payment of the installments on the capital invested of 2 per cent, thousands of landowners plead that they cannot keep up this rate of installments. Last year 2,000 appealed for relief, this year over twice as many. There is no doubt but that many of the settlers do need help, on account of excessive cost of the project, poor soil, small yield and the like, but those unfriendly to the reclamation policy argue that the beneficiaries under the Reclamation Act should be required to meet their payments or accept terms comparable to those of the Federal Farm Loan Act, amortizing the debt in from 30 to 40 years but with payment of a small interest, equivalent to the amount the taxpayers are carrying on money borrowed by the government.

The annual relief bills will probably come before Congress as long as there remains any debt to the United States, unless some general rule should be laid down consistent with sound business principles, and the commissioner of the Reclamation Service or a board given the power and duty to establish regulations for adjustment of payments after a thorough investigation

has been made of the necessities of the settlers on the different projects and to see that these regulations are carried out in a spirit of fairness.

Co-operation Between State and Nation—One of the chief criticisms of the Reclamation Act is that it is too one-sided. The federal government is furnishing all the money, doing all the work, is being criticized because it does not enter into more details, while the state is doing little or nothing in the way of solving the problems of its citizens on the reclaimed lands.

Undoubtedly there will be better appreciation of the work done by the government if much of this is made contingent upon the performance of equally important functions which fall within the state jurisdiction. The selection of settlers, getting the reclamation lands into the hands of men who will actually use them, providing advice toward better crop production—all of such work and many other details should be handled to a larger extent by the state or state organizations, farm bureaus, and others. The national government should be in a position to deal with the state or municipality organized under state laws and not be put in the position of supervising the details of water distribution to thousands of farms.

In particular, the financing of the settler is a matter which should be taken up by the state. Under present conditions, the landowners must borrow considerable sums of money, on which they are paying 8, 10 and 12 per cent, a rate which it is impossible to continue for any considerable time without injury. There are many arguments why, if the federal government will provide the water, the state or its subdivisions should give proper attention to these financial needs.

Taxes—In addition to the heavy interest charges for which relief should be offered, there are the steadily increasing taxes which are piled on the back-breaking load of the irrigator. Remember that the greater part of the taxes is of local origin, state and county. These taxes are under local control and yet they have increased with such rapidity that many an otherwise well-to-do farmer has been compelled to give up, the taxes representing a proper margin of profit.

The reason for this heavy taxation is evident in that on the reclaimed areas the people in the towns especially have demanded the conveniences of a highly settled community. They are building roads, bridges, schools and public buildings surpassing those of communities which have been settled for a hundred years. They are trying to pay for these things in a few years. All of them are desirable, some are necessary; but more necessary is it to keep the taxes within the limits where they can be paid.

A Vision of the Future—In what I have written I have tried to point out the things which should be done, and it might be inferred that, because I have pointed these things out, they are the large features of reclamation. On the contrary, while important they are not the whole story. I have not taken time to amplify upon the advantages and the great opportunities which lie before us in the future. I am merely pointing out the bad places in the road. At the same time the road does lead through pleasant valleys and has great attractions. It leads to far better conditions than I have touched upon. We are only at the beginning of land reclamation. We will realize even more largely than in the past the vision of the men who work for reclamation and the making of farm homes. We will ulti-

mately achieve these but we can do so more quickly and more satisfactorily to all concerned if we consider the rough spots and smooth them out.

The country as a whole not only needs more opportunities for homes but can provide these opportunities to be taken up in an orderly manner as needed, when we make use of the experience we have had in the last twenty years. By utilizing that experience and by doing some of the things which I have described, we will be performing not only a necessary duty but one which will redound to the peace and prosperity of the whole nation.

Dining-Car Train Serves Mid-Shift Meal to Tunnel Crew

TWO OF THE headings on the 13-mile Florence Lake tunnel, which is being constructed by the Southern California Edison Co. on the Big Creek project are now two miles underground. Because of the distance from the portal camps a great deal of time would be lost in taking the tunnel crews out to their mid-shift meal. Moreover, from the point of view of the workmen there is serious objection in the winter time to the long ride and cold outside air, without time for a shower which they would take when coming off duty, thus both the crews and the company are highly pleased with a plan recently put in effect whereby the tunnel crews are supplied with a hot mid-shift meal served in the tunnel near the heading.

This plan has been made possible by the construction of dining-car trains, one of which is shown in the accompanying picture. This train is composed of five cars, three of which are equipped with tables and benches as shown, the other two being designed to carry the food into the tunnel and for use there as serving tables.

The food is transported in containers originally built for army use, which utilize the fireless-cooker prin-

MESS TIME IN FLORENCE LAKE TUNNEL

ciple in keeping the food hot in transit. Two waiters accompany each train, make the "set-up" prior to the meal, replenish the dishes and afterward clear up and return the utensils to the cook house at the portal camp.

Each dining-car train is handled by an extra locomotive so as not to interfere, in any way, with the mucking operations. Needless to say the inbound dining-car train does not meet with delay en route if the tunnel crew can prevent it. Under present conditions

it would take a minimum of 1½ hrs. to bring out the crew, give them time to eat and return them to their work. This time, of course, would increase as the heading is advanced. The new arrangement takes the men away from their work only for the length of time required to eat. The plan was put into effect in November and was very popular with the workmen from the outset, as now they do not have to come out into the cold air until they can go direct to their bunk houses.

Construction methods on the Florence Lake tunnel were described in *Engineering News-Record*, May 3, 1923, p. 776. The work is being done by force account for the direction of D. H. Redinger, resident engineer, for the Southern California Edison Co.

Ballast Sections on French Railways

AN INCREASED depth of ballast has been adopted on several of the French railway systems as a result of the greater weight of modern locomotives and rolling stock. This change is noted in the *Revue Generale des Chemins de Fer* by M Descubes, maintenance engineer of the Eastern Ry., and it is pointed out that the engine loads do not reach those of American railways. Formerly the depth under the tie was about 9 in. on straight track (sometimes only 7½ in.) and 6½ in. to 7 in. under the lower ends of the ties on curves.

In the new roadbed and ballast section of the State Rys. the ballast depth is 10 in. under the ties or 15.6 in. from top of tie. This is also the minimum depth under the low rail on curves. On double track the depth is 14.6 in. at the crown or middle of roadbed and 18 in. at the shoulders. The Southern Ry. uses an 8-in. bed of sub-ballast and a minimum of 7.3 in. of ballast proper. A similar construction on the Eastern Ry. has 8- and 6½-in. depths respectively. In all cases the ballast is level with the tops of the ties and has a shoulder 32 in. to 36 in. outside of the rail. Formerly this distance was 39 in. to 48 in., with a view to affording lateral support to the track, but it is now considered that the value of such a shoulder is relatively small. Where a bottom course of sub-ballast is used, it sometimes extends the full width of roadbed and forms side berms outside the ballast proper.

A conference of engineers of maintenance-of-way in August, 1923, adopted conclusions which are summarized below:

1. A thickness of ballast sufficient to distribute the load uniformly over the roadbed will avoid maintenance work on operated lines the cost of which work would be out of all proportion to the slight saving by using less ballast. On new roadbed the thickness of ballast and sub-ballast should be at least 14 in. under the tie at the rail. This depth may be reduced when the roadbed material is both stable and permeable, but on irregular rocky roadbed it should be increased, since a good cushion of ballast will reduce rail breakages. On an old roadbed, compacted and drained, a thickness of 10 in. under the ties may be sufficient.

2. A width of 32 in. from rail to shoulder of ballast is sufficient, but may be made 39 in. on new lines to provide a reserve of ballast in surfacing.

3. The ballast proper should be at least 6 in. deep under the ties. Sub-ballast should be of a finer material but sufficiently permeable for drainage.

4. Transverse crowning of the roadbed with grades of 0.3 to 0.5 per cent is advisable for drainage. On curves, the summit or high point may be placed under the outer track to avoid excessive depth of ballast.

Deep Water Pile Driving for Seattle Bridge Piers

Good Progress Made on Pile Foundations for Spokane Street Bridge—Convenient Form of Follower Head Saves Time

THE CITY of Seattle now has under construction the Spokane St. crossing of the West Waterway which will be a bridge for vehicular and electric railway traffic, having for its central span a 238-ft., double-leaf bascule. Despite the depth of water around the piers for this central span, which required the use of an unusually long follower, good speed was made in driving the piles. In an ordinary eight-hour shift 20 piles or 1,700 lin.ft. of piling were driven using piledriver leads much shorter than the average length of the piles themselves. Piles were driven through silt to hard bottom 130 ft. below mean high water.

The order of procedure found most satisfactory was as follows: A derrick with a 90-ft. boom picked up the piles, which averaged about 85 ft. in length, and delivered them to a skid-rigged driver. Before taking the pile the driving crew put down between the driver leads a jet consisting of a 5-in. pipe, 100 ft. in length, in which a pressure of 250 to 300 lb. was used. This pipe was put down for each pile, first to the full depth and then thrust down three or four times to depths of about 40 ft. The bottom was hard enough to shut off the water pressure abruptly, making further jetting impracticable. Ordinarily this operation required about 3 or 4 minutes for the first long thrust and about one minute each for the thrusts to a lesser depth, and carried the top of the 100-ft. pipe as much as 30 ft. below the top of the cofferdam shown in the illustration.

The jet was slung from a block attached on one side of the leads near the top so that, as soon as the pipe was lifted and the guy line holding it between the leads was slacked off, it would swing out of the way of the pile which would then be put in the leads as quickly as possible so as to get it down in the jetted hole before there was time for the hole to fill up. The pile was simply centered in the leads and dropped; about 90 per cent of the time piles handled in this way went down into the jetted hole until supported by their own

buoyancy, that is, the pile would float upright in the hole made by the jet and would remain with 15 to 20 ft. of its upper end projecting above water level. The cofferdam had been excavated to a depth of 53 ft. below mean high water.

By using a cast-iron head of the type shown in the accompanying sketch no time was required in centering the head on the pile because of the taper section in which the specially prepared heads of the piles would center themselves. The pile heads were all axed off while drawn up on the deck of the floating driver by a boom-man and helper, this axing giving the pile head a taper corresponding with the taper in the iron head.

The head shown in the sketch was attached to a selected 18-in. fir follower, about 60 ft. long, to which it was fastened by four 1-in. bolts driven into the follower through holes in the casting. The follower with the head attached was put on the pile immediately

ELEVATION THROUGH CAST-IRON FOLLOWER HEAD

after the latter stopped sinking of its own weight. The weight of the follower caused it to sink still lower, in fact always low enough so that the hammer could be placed upon the follower. In driving 560 piles there were only two cases where the head stuck to the pile.

The hammer was a 4,500-lb. drop hammer. This was ordinarily used about ten minutes on each pile with blows varying from 8 to 10 ft., which was sufficient to give the 85-ft. piles a penetration of 50 to 60 ft. in addition to the depth they had sunk in the jetted hole.

The floating driver was used only on account of its pump equipment which supplied water for the jet. The derrick was so placed that it could pick up a pile and place it vertically alongside the driver leads where it would hang until the jet pipe was removed and the pile could be swung into the leads. After delivering a pile to the driver the derrick picked up the follower and held it suspended ready to place in the leads on the pile. This saved time.

The driving crew consisted of one foreman, one stationary engineer on driver, one stationary engineer on pump, one boom-man and helper preparing pile heads, three lofts-men, one man on winch handling line—a total of nine.

The work was done by the J. A. McEachern Co., contractors, J. A. McEachern, president, and B. F. Cook, general superintendent. The project as a whole is under the direction of J. D. Mackwell, city engineer. A. Münster is bridge engineer for the city and E. K. Triol is supervising engineer in charge of construction for the city.

DRIVING LONG PILES WITH A FOLLOWER

The derrick boom is ready to deliver pile to the driver on the right from whose leads the jet pipe is being removed. The driver at the left is used only to pump water for jetting.

Through the Reclamation Country

By F. E. Schmitt
Associate Editor, *Engineering News-Record*

THIS is the twelfth and last of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

Chicago

MANY illuminating opinions on irrigation and reclamation were expressed in the course of the interviews I have had during the last two months in the irrigation country. They are the views of men who have lived in contact with irrigation farming and its successes and troubles for many years, and who have seen the endless promotion, mismanagement and confusion of private irrigation work as well as the much troubled development of federal work. Moreover, these men are familiar with the farmer's problems and his psychology.

Because the opinions expressed in these interviews give an excellent perspective of the irrigation situation, a selection of citations from them will help the engineering reader in appraising the present reclamation situation. Names are omitted.

Success in reclamation farming comes to the same kind of people that would succeed on other farms; and in ordinary farming there are always many failures. I can't see how the weeding-out process is ever going to be avoided in reclamation. The successful farmer can pay the construction charges, the others can't.—*Grand Valley farmer.*

The statement that it takes from two to three crops of settlers to make an irrigation project a success is specially true of private projects. All have been failures, in some cases again and again. The few exceptions were cases that had the best land and the simplest and cheapest water supply.—*Former state engineer.*

The Congressional relief acts did not work well here. Many people applied for relief who could pay but thought they would never have to.—*Project manager.*

Eighty per cent of the settlers here weren't farmers, and these are mostly gone. The other 20 per cent, the farmers, are still here.—*Water users' official.*

I believe the Reclamation Service never took the trouble to see that in starting up an irrigation project there lay problems that it was their obligation to solve even at the cost of stirring up Congress to improved legislation and a change of system.—*Engineer farmer.*

Farm debts are probably in good part due to inflation and deflation, but in part to the farmer's inability to make his farm pay. The men that came here were the skim-mings of farming and other communities. As the records show, it was largely the failures in business elsewhere that came to try farming on this project. There is some real sentiment that the farmers should not pay the construction charge, but most of the protest sentiment is created or magnified by political agitators.—*County attorney.*

A large part of the farmers' difficulties here is due to speculation in sheep and land, and some in oil, during the war boom of prices. Those who took their crop money to pay their debts are not grumbling now.—*Project manager.*

Probably no other region of the same size in this valley is as good as ours in soil. Yet last year we had to sell 120 tax titles, and this year we will sell 20 more, and probably few of these will be redeemed. They include some

of the best land on the project here.—*Water users' board member.*

Outside of not enough water in July, our trouble is lack of capital, inexperienced farmers and high freight rates. In shipping our produce we are like the last man on the ditch.—*Chamber of Commerce manager.*

The reclamation projects are not failures in agricultural productiveness. They are well located, have a good water supply, and are operated economically. But in constructing them the government created an increment of value, and by putting no bar to transfers it encouraged land speculation. That is the root trouble.—*Private project manager.*

People in irrigation regions are enthusiastic about irrigation when they haven't got it and want money to provide it. Afterwards they complain. At Yakima farmers on private ditches pay \$10 per acre, those on the government projects \$2 to \$3, but the latter protest while the former pay. The settlers' attitude toward their obligations is an essential element in the whole problem.—*Irrigation engineer.*

Water users might operate more cheaply than the government, through eliminating the overhead of the outside offices. But if any emergency happened, the water users might not have the means to handle it. This makes government operation safer for us.—*Umatilla farmer.*

All talk about the condition of the farmer is largely an outburst of something that has been seething for a long time. The price unbalance is at the root of it.—*Banker.*

The engineers on this project were learners, and naturally they had to cover up their mistakes. At that time and later the farmers had the difficulty of not being able to reach the higher ups.—*Newlands farmer.*

A man who gets right down in the dirt and roots can't fail to make a success in irrigation farming here.—*Another Newlands farmer.*

From my experience in private irrigation and on this project I would say that people here are the same as elsewhere except that they lack the habit of self-help. The government has given so much relief that whenever anything happens they look to the Reclamation Service to help them out and take care of them.—*Irrigation superintendent.*

We have many kickers, usually kicking about nonsensical things. One fellow objects to drainage construction, and wants the river excavated to do away with flood dangers. We also have farming failures and these must be weeded out. There is no way of avoiding or shortening this process. But even apart from this, we still have far to go; we need more dairying, more poultry, and more truck farming, and we need farmers who like and understand these branches.—*Southwestern merchant farmer.*

The experiment station and the project office teach the doctrine of cow dung, elbow grease and butter fat. Alfalfa is worth twice as much when fed here as when shipped out. Every farmer who has good cows, tends to them decently and understands them, is getting along and is paying his bills.—*Project manager.*

Our project is a thorough success, taken altogether. But we have howlers, some because they are failures and others because they are such by temperament; none of them has constructive ideas. I doubt whether the unsuccessful farmer can be helped by advice or guidance. The chief trouble is that our people are not high-grade enough. We need more of the spirit of self-help and the spirit of co-operation.—*Southern banker.*

When the Reclamation Service warned the farmers on this project of the need for drainage, the warnings were not believed, and the farmers took no action for several years. Their losses from this neglect exceed the total construction cost of the project. But some farmers now want to blame the Service for not cramming drainage down their throats.—*Water users' official.*

The Federal Land Bank discriminates against project lands. It will loan on private irrigation land but refuses to loan on a federal project close by.—*Project manager.*

We are afraid that the project farmers have become

imbued with the idea that there is no need of paying the water charges, as they have always been able to secure extensions and deferments.—*Land Bank official.*

The reclamation farmer is too heavily burdened with debt. His average debt per acre is equal to or greater than the annual production; it should not exceed half this amount. The debts are not due to pioneering, but to speculative buying. Further, the farm regions have gone too fast with public improvements, which makes bonds and taxes too high. But farm land values are apt to ignore both the government equity and the tax rate. As to the farmer's attitude toward his obligations, and its effect on his credit, the facts speak clearly enough; the desire to evade obligations is there, and it weighs in the granting of loans. Aside from this factor, debt and inflation conditions are nearly the same in other recently developed agricultural districts.—*Federal Land Bank official.*

In considering applications from reclamation projects we apply just the same rules of sound appraisal as to private irrigation land. Due weight is given to the moral hazard. The bank is apt to regard the reclamation farmer as a less desirable borrower than an irrigation district farmer, because of the former's persistent attitude of disregarding his contractual obligations.—*Land Bank appraiser.*

The ones that don't pay and want relief are those who aren't good farmers.—*U. S. Senator.*

Perhaps 25 to 30 per cent of all our farmers are kickers, but most of these also are heavily in debt and are not succeeding. When they get out of debt they reform.—*Irrigation manager.*

Farming, like any business, requires some capital to start. Neither now nor never can the farmer get any other start than through his own effort.—*Banker.*

The man who has only \$1,000 shouldn't expect to come here and make a go of it. This irrigation farming is not a poor man's game.—*Banker.*

Liquid financing is absolutely insufficiently provided for.—*Water users' official.*

Any farmer in sound condition and really in need of working credit can come in here and get all he wants.—*Banker.*

I don't believe you can select the good farmer at the start; but you can tell him by the results after three years, and then the government should weed out the unsuccessful ones by foreclosing the lien.—*Water users' official.*

Some years ago much land here in the Northwest was sold to clerks who thought they needed only to tickle the soil to become rich. When they found that they had to work two or three years they gave up.—*Washington engineer.*

Irrigation is often pure exploitation of people who have become obsessed with the back-to-the-land idea. Managers of irrigation developments either should keep out the unfit or they should teach them. These Carey Act projects, in particular, have even a more miscellaneous lot of people than government projects. One of the greatest hardships is the lack of a home at the start, with the result of throwing an excess burden on the wife; possibly half of the people who pulled out of here did so because the wife became discouraged.—*Idaho engineer.*

The Carey Act system appears to have failed. Successful for a short time, it was soon made speculative, and inadequate preliminary study of water, soil and cost became general. There are only one or two successful Carey Act projects. Fundamentally, it is the best system for reclaiming *raw desert*. The district system is good for operating, or for rehabilitating an area already settled.—*Oregon engineer.*

The federal reclamation enterprise is partly responsible for the failure of private irrigation. It gave a general boom to irrigation, which led to unhealthy conditions, failure to study water supply carefully, easy marketing of bonds, and the like, with disappointing results, which led to financial collapse. In other cases the difficulty of raising funds led to the hiring of low-priced engineers, which in turn resulted in dam failures and other ruinous results.

It might have been better to let irrigation work out by evolution rather than to develop new areas under the impulse of federal reclamation.—*Colorado engineer.*

In one respect we enjoy an advantage over the government projects. We are not hampered by politicians. If the government doesn't eliminate this trouble and settle down to a fixed practice, all irrigation will suffer. We close out the failures promptly. The government can do the same thing; and it would, if it were left alone by the Secretary.—*Private project manager.*

Most of the farmers here are satisfied with ordinary crop yields. They overlook the fact that high production is necessary if they are to clear their obligations.—*Nebraska engineer.*

Where land before irrigation is worth only say \$15, the attempt to bond it under an irrigation district for \$60 to provide irrigation is questionable. The process involves the assumption that the land will be benefited correspondingly. Security for the bonds does not exist to begin with, and may not exist even after the loan has been made and expended. Yet this is widely done.—*Oregon engineer.*

The advocates of the \$350,000,000 reclamation plan with forty-year repayment and 5½ per cent interest will have to hunt up much better projects than the present ones if they want them to pay out.—*Project manager.*

A fatal error is embodied in the reclamation system: charging the farmer no interest on the construction cost, which removes all incentive to pay when he has money available.—*Former state engineer.*

Two serious mistakes of past reclamation practice were that the government allowed entry on land before water was available, and that it dealt direct with the individual.—*Congressman.*

The reclamation policy as relieved by the twenty-year amendment and the extension act has worked out very well. The only matter in which its administration has been a little remiss is colonization and attention to the farmer. Thirty-year payment at the discretion of the management should be authorized, with interest at say 4 per cent. It may be necessary to write off some losses; but we should not put any permanent government investment into irrigation, for that would pauperize the farmer.—*Washington engineer.*

There is no room for a middleman between the water and the farmer.—*Mid-West Senator.*

It is the government's business to increase the water supply of the arid regions, but it is not the government's business to operate irrigation systems.—*Agricultural engineer.*

I see no way to cut government red tape in such work as operation of reclamation projects.—*California engineer.*

The reclamation fund was raised from Western lands and belongs to the West. We've got the reclamation fund, and you birds down East just try to get it away from us!—*State official.*

Two essentials of a reclamation policy are projects that will enable the average farmer to make a decent living when the costs are paid, and protection of the original owner from the temptation to borrow money at high rates and to sell for speculative profit.—*California engineer.*

Our people have cursed the government a lot, but at the same time when they sit down and think things over, they know it is all right.—*Yuma farmer.*

One fault in the original reclamation law was that it is not fair to private irrigation. The law should have provided for construction of storage only, leaving distribution to private initiative. It should have provided for interest payment, to be fair to private irrigation. It should have required selection of settlers for available capital, farming experience, attitude of wife, and the like. And the law should have put more freedom of action into the hands of the secretary. As to financing the settler, I see no ready way of doing it through the federal government. Development of the projects would be best handled by state settlement and state financing.—*Agricultural engineer.*

Engineering Literature

A MONTHLY REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Concrete Ships

REVIEWED BY S. C. HOLLISTER
Consulting Engineer, Philadelphia, Pa.

SEAGOING AND OTHER CONCRETE SHIPS—By N. K. Fougner, C. E., M. Am. Soc. C. E., Medlem Norsk Ingeniør Forening, Assoc. Inst. N. A. London: Henry Frowde and Hodder & Stoughton, New York: Oxford University Press, American branch, Cloth, 6x10 in.; pp. 216; halftones and line cuts. 22s.; American price, \$7.

This constitutes the first important book on the single subject of concrete ship construction. It comes from the pen of an engineer who has been actively engaged in this type of construction for more than a decade, and who enjoys the distinction of being the builder of the first seagoing concrete ship, the "M. S. Namsenford."

The book, while it relates the progressive experiences of the author's work, is especially valuable in that it discusses frankly the advantages and disadvantages of concrete ships and minor service craft in commercial competition with wood and steel vessels. It is significant that in the world at large the concrete ship was not a product of the World War, but rather that its beginning was rooted in the peace time prior thereto. Whereas the war greatly stimulated the building of large cargo carriers, the post-war reduction in shipping together with the over production of vessels will probably prevent, in this country at least, the thorough operating trial that this type of vessel would receive in time of normal shipping. It is quite likely that the commercial aspect of the concrete ship will be determined earlier in Europe than in this country, because private interest in it there is more general, and because it was being seriously developed in time of peace. The book gives ample evidence of the two outstanding facts that concrete ships can be built on a commercial basis, and that they are seaworthy.

The author goes into considerable detail concerning the design and construction of vessels built by him, and summarizes, also, the design and construction of the U. S. Shipping Board's concrete ships. He presents many data on the properties of concrete, pertinent to ship construction, including the use of special lightweight aggregates.

Considerable discussion is also presented to show that the author has achieved in his construction vessels whose ratio of unloaded weight was less per ton of cargo than those built by the U. S. Shipping Board. It should be borne in mind that the latter vessels were designed to carry from three to six times the cargo of the largest of the author's vessels; and that no concrete ships of anything like their size had been built prior to their undertaking. There is little doubt that, had the program been continued, considerable economies in weight could have been effected as experience was acquired from the earlier vessels. Within certain limits, pioneer engineering in any line sacrifices economy in the interest of assured safety, and economy will only come as a refinement gained through experience.

There is presented a very interesting discussion of barges and lighters, together with well-established conclusions as to the advantages and economy of concrete craft of this class.

It is hoped that this book will outlive the present shipping situation in this country, to the end that its justified usefulness will be constructively available to those who are bound at some future time to continue the development of concrete craft. Certainly in those countries where the shipping is again finding itself, the book will present much of importance in developing in a sound commercial way the building and use of concrete ships of moderate size.

Earth, Sun, Climate and Civilization

REVIEWED BY X. H. GOODNOUGH

Chief Engineer, Massachusetts State Board of Health, Boston

THE EARTH AND THE SUN: An Hypothesis of Weather and Sunspots—By Ellsworth Huntington, Research Associate in Geography in Yale University. New Haven: Yale University Press. London: Humphrey Milford-Oxford University Press. Cloth; 6x9 in.; line cuts. \$3.50.

CIVILIZATION AND CLIMATE—By Ellsworth Huntington, Author of "The Pulse of Asia." [Second Edition, with New Introduction.] New Haven: Yale University Press. London: Humphrey Milford-Oxford University Press. Cloth; 6x9 in.; pp. 333; line cuts. \$3.50.

CLIMATIC CHANGES: THEIR NATURE AND CAUSES—By Ellsworth Huntington, Research Associate in Geography in Yale University, and Stephen Sargent Visher, Associate Professor of Geology in Indiana University. New Haven: Yale University Press. London: Humphrey Milford-Oxford University Press. Cloth; 6x9 in.; pp. 329; 13 line cuts. \$3.50.

Earth and Sun, is a companion volume to the author's earlier Climatic Changes and should be read in conjunction with it in order that the general discussions and data presented may be intelligently followed. In Earth and Sun, the author illustrates very clearly and submits diagrams which indicate a close relation between solar disturbances and terrestrial temperature. He presents also studies of the relation of solar conditions to climatic variations, storms and electrical activities. This volume no doubt would be of less interest to the engineer than to members of certain other of the scientific professions but is of value to those engineers who are interested in studying the causes of the various climatic changes, including the distribution of moisture and variations in temperature.

The results of the study showing the relation of sun spot occurrence to rainfall are not conclusive so far as the rainfall in the northeastern part of this country is concerned, but such a comparison is difficult because of the limited period available for comparison as presented in this volume. Further study along the line indicated would be of great interest and might prove most valuable.

The correlation of data in this book must have required much research work on the part of the author, and the results of his interesting studies should encourage further investigation along the same lines.

Civilization and Climate, now in a second edition, is an investigation of the influence of certain climatic

conditions upon health and industry in various parts of the world and is interesting to engineers as well as to geologists, geographers, meteorologists, historians and others who have made less general studies of similar subjects. The writer traces a connection between climate and health, especially in human progress, in a very interesting way. It is somewhat unfortunate, however, that more detailed information is not presented in the appendix to assist those readers who might be interested in ascertaining the facts from which the conclusions in this volume are derived. The addition of this information would have enabled students of the subject to carry the matter further and make other comparisons without going over again the data from which the information was collected. It is hoped that certain other volumes which the author is about to publish may include the exceedingly valuable information which he has collected.

Large High-Speed Reservoir Outlets

HIGH-PRESSURE RESERVOIR OUTLETS: A Report on Bureau of Reclamation Installations—By J. M. Gaylord, Electrical Engineer, and J. L. Savage, Designing Engineer, Washington, D. C.; Bureau of Reclamation. Part I: Cloth; 6x9 in.; pp. 179; 32 halftone plates and 44 figures in the text. Part II: Cloth; 8x11 in.; folding plates of detail drawings. Part I, \$5; Part II, \$10.

One of those rare government reports that form basic contributions to technical literature has been produced by Messrs. Gaylord and Savage. Their detailed account of Reclamation Service experience with large-volume, high-head valves and discharge conduits contains a record of practice unequalled by any other treatment of the subject. It promises to remain the principal document of the subject for many years to come. Their work is distinguished also by a clearness and simplicity of statement that makes the report additionally remarkable. An album of drawings accompanying the text increases its value and scope well beyond that of the ordinary text-book.

In attacking their subject the authors begin with a simply stated outline of its elements; the growth of the reservoir-outlet problem from early ages, the application of butterfly and simple gate-valves, and finally the development of large slide, cylinder and needle gates. Still following the schematic plan of presentation, they next describe the various types of outlet arrangement, involving the position of the valve, with reference to the discharge conduit and the provision of means for admitting air to weak vacuum and for getting at the valve to inspect or repair it. Losses in outlets are briefly discussed and some data are given concerning high-head outlets for large discharges.

The detailed treatment then takes up in succession the various valve types, most space naturally being given to the needle type, in view of its dominant position in this field. Then follows as the main part of the book a series of chapters dealing separately with outlet development at various high dams built by the Reclamation Service. The troubles encountered, how they were dealt with and to what extent they were solved are treated in full. This is the part of the book that assures its permanent position in the literature of engineering and entitles the authors to the thanks of the profession.

A section of quite independent value, printed as an appendix, is a bibliography of reclamation articles and books on irrigation, including in 33 pages several hundred entries.

Filtration Broadly Considered

REVIEWED BY ROBERT SPURR WESTON

Consulting Engineer, Boston, Mass.

A TEXT BOOK OF FILTRATION: Industrial Filtration and the Various Types of Filters Used—By Charles L. Bryden, E. M. B. S., and George D. Dickey, B. S., Easton, Pa.; The Chemical Publishing Co. Cloth; 6 x 9 in.; 264 halftones and line cuts. \$5.50.

As stated in the Preface, this book was written "to give the fundamental principles underlying filtration, the modifications necessary under varying conditions, the proper procedure for carrying on experiments, the available data on filtration and a description of the various types of filters which have been developed as a result of scientific research."

In the Introduction, the authors assume the particles of precipitates to be spheres for the purpose of making clear the theory of the art, yet are not misled into assuming that all particles of like volume offer equal resistance to filter media. Twenty-four clear photomicrographs of precipitates illustrate the variations both in size and in nature of precipitates. The importance of microscopic examination in filtration problems is well developed. The relations between rate of flow, pressure and cake thicknesses are well illustrated by tables and formulas and the influences of viscosity and temperature concentration are likewise mentioned.

The practical laws of filtration given are: (1) As open a filtering medium as possible should be chosen. (2) If possible in any way to control precipitation prior to filtration microscopic examination and experiments should be carried on to determine the best form of precipitation for filtration. (3) In filtering non-rigid solids care must be taken to build up the pressure gradually and uniformly. (4) High pressures do not necessarily give hard dry cakes. (5) A thin cake offers lower resistance than a heavy and consequently gives a higher rate of flow, and easier washing and drying. (6) The cake should be as uniform in porosity and thickness as possible in order to get good washing and drying. (7) Lack of proper agitation in leaf filters gives pear-shaped cakes, and uneven or partial filling of a filter press produces a cake of varying porosity and thickness, both of which are undesirable. (8) The higher the temperature the lower will be the viscosity and consequently the greater the capacity of the filter.

The book contains an interesting history of filtration with a page devoted to the development of water and sewage filters. About eighty per cent of the space is occupied with descriptions of dewaterers, clarifiers, filters and presses, for removing the suspended matter from gases and all sorts of liquids—aqueous, oleaginous and organic. Indeed the spirit of fairness has led the authors into redundancy in describing so many makes of the same types of apparatus. For example, there are quite detailed descriptions of the products of a dozen makers of water filters and it is rather unfortunate that the apparatus are described with the makers' names rather than types of filters as headings.

The chapter on Centrifugal Machines contains valuable information, although it bears a strong resemblance to catalogue announcements, and the chapter on Air, Gas and Light Filters should be read by those who use air for the agitation of sewage and other liquids. Even the Cottrell process and color screens are described briefly. Laboratory filtration has a chapter devoted to it but there is no mention of the new "stream-line" filter.

In their chapters on Leaf and Frame and Leaf and Rotary Filters the authors have compiled much valuable information which, while of greater interest to the industrialist than the public-health engineer, should not be overlooked by the latter when studying the problems of dewatering and partially drying sewage sludges and the precipitates from factory wastes.

The chapter on Coagulants and Filter Aids is rather disappointing. The reviewer had hoped to read a popular statement of modern theories of coagulation but the theory of the past decade is employed. There are some good diagrammatic operating data given in a special chapter and descriptions of thickness, pumps, coagulant feeders, compressors, etc., are not wanting. Some good tables, useful for filter operators and others, are contained in the Appendix, among them one giving the proper materials and fittings to be used for pumps for handling various liquids, corrosive or otherwise.

While the book will be read more by mechanical and chemical engineers than by civil engineers, the reviewer commends it to all interested in filtration, especially to those sanitary engineers who have to dispose of troublesome solids. The expert on water-purification will find better information elsewhere.

Early Effects of the Steam Engine

CAPITAL AND STEAM POWER, 1750-1880—By John Lord, Bachelor Scholar of Christ's College, Cambridge. London: P. S. King & Son, Ltd. Cloth; 5x8 in.; pp. 253. 75s. net.

With its full references to the original sources from which the greater part of its historical data were taken, this book is not only interesting as an historical document but is also an engaging account of the development of the steam engine and its introduction into the industrial life of England. As a background, the author has outlined the conditions in trade and industry in the period immediately preceding the introduction of steam power and the development of the capital system up to that time. Then comes a description of the early developments in atmospheric steam engines and their application to and effect on industry. This leads to an account of the development of Watts' engine, the method of financing it, and the uses of this improved means of power in developing the basic industries of the country. The book closes with a review of the condition of capital and labor in 1800 and a discussion of the importance of the work of such energetic men as Watts in raising the standards of industrial life to their present level.

Spanish Railways

THE RAILWAYS OF SPAIN—By George L. Boak, Author of "Manual of Railway Statistics." London: The Railway Gazette. Cloth; 6x9 in.; p. 129; halftones and line cuts. 12s. net.

The Railways of Spain, as the title would indicate, is a description of the Spanish railways from the time of their inception until the present day, with a discussion of their future and of nationalization and government intervention. The author's knowledge was gained during several years of experience in the management of a railway in Spain. The book gives the essential facts concerning the railways, starting with the original construction and financing by the aid of government subventions and continuing with a discussion of present-day conditions, earnings, fares and rates, and descriptions of typical structures and equipment. The last chapter is devoted to a brief outline of the railways of Portugal.

This is a book that should be read by all advocates of government ownership, because of its exposition of the results of "too much government" in the railways.

Tremors and Noise Caused by Machinery

THE PREVENTION OF VIBRATION AND NOISE—By Alec B. Eason, M.A. (Cantab.), Assoc. Inst. C.E., A.M.I.E.E. (Oxford Technical Publications.) London: Henry Frowde and Hodder & Stoughton; New York: Oxford University Press. Cloth; 6x9 in.; pp. 163; 65 halftones and line cuts. \$5.

Tremors and noise transmitted from moving machinery through buildings or through the ground are the author's subject in this work. His text is essentially a bibliographical summary of what various people have studied and written on this topic. Its perusal gives a definite impression of the primitive state of the subject, but for this very reason the book may prove a convenient starting point for many who will have to deal with practical problems in transmission of tremors.

PUBLICATIONS RECEIVED

VENTILATION OF CENTRAL STATION BUILDINGS AND EQUIPMENT, a report of the subcommittee on ventilation of the Electrical Apparatus Committee, Technical National Section of the National Electric Light Association, is a study of the laws governing the movement of air and their use, both in present practice and in proposed installations, for the ventilation of central station buildings and prime movers. The paper gives a number of diagrams of air movement in typical installations and tables of air duct sizes, also a description of various types of ventilating machinery. (National Electric Light Association, New York City; 25c. to members; non-members, 40c.)

THE INSTITUTION OF CIVIL ENGINEERS (London) has issued a second supplement to its investigation on the Deterioration of Structures in Sea Water, called The Third Interim Report. The latest appendix gives further reports of the behavior of steel in wood, in sea water, in various marine exposures of the British Empire and throughout the world. Concrete is not discussed. (London: H. M. Stationary Office; 3s. 2d.)

THE VERY HEAVY REINFORCED-CONCRETE SLAB BEAMS tested during the war in the interest of concrete ship construction have been made the subject of Technologic Paper No. 233 of the Bureau of Standards (Washington, D. C.) entitled Tests of Heavily Reinforced-Concrete Slab Beams, Effects of Direction of Reinforcement on Strength and Deformation, by W. A. Slater and Fred D. Seely. The results give some useful information on the behavior of diagonal reinforcement in thin slab beams.

LAST YEAR at the American Concrete Institute, Prof. W. K. Hatt, of Purdue University, gave some preliminary information on studies to prove the value of the ball test as a determinant of the quality of concrete. More elaborate notes on these tests are now supplied in a bulletin entitled Ball Test Applied to Cement Mortar and Concrete, by R. B. Crepps and R. E. Mills. (Purdue University, Lafayette, Ind.)

THE UNITED STATES BUREAU OF MINES (Washington, D. C.) has issued a Bibliography of Magnesite Cement, by G. H. West, R. L. Sebastian, and W. A. Darrow. It was compiled in the course of research work on the utilization of magnesite in the West.

THE DEPARTMENT OF COMMERCE, Bureau of Foreign and Domestic Commerce, has issued as miscellaneous series No. 119 a bulletin on Inland Water Transportation in the United States. It has a prefatory section on the economics of inland waterway transportation generally favorable to that neglected field, and is followed by a categorical descrip-

tion of all of the waterways in the United States and an appendix giving a digest of the various governmental reports on inland waterways.

DR. J. A. L. WADDELL delivered two addresses at Brown University in September, the first entitled *Some Observations on the Regeneration of China* and the Engineering Work Involved Therein, and the second, *Functions of Both Pure and Applied Science in the Future Development of China*. Both of these are now available in one small volume. (The author, 35 Nassau St., New York City.)

ELEVEN 20x14-IN. CHARTS in a flexible loose-leaf binder have been prepared by E. V. Willard, Commissioner of the State Department of Drainage and Waters, St. Paul, Minn., giving the flow capacities of ditches and tile drains of various sizes and slopes. There are also three sheets of text. These charts have been prepared under a state law which authorizes the department to issue and publish "rules and regulations" for the information and guidance of officials in public drainage proceedings operating under the state drainage laws. The intention, therefore, is to furnish them only to engineers within Minnesota. They are not for sale and the extent to which outside engineers can be furnished with the charts is left to the discretion of the Department. There is only a limited edition.

THOSE WHO HAVE OCCASION to use population figures will welcome the Census Bureau's *Estimates of Population of the United States by States and Cities, 1910 to 1923*, and Area July 1, 1923 (15c. from Superintendent Public Documents, Washington, D. C.).

INDUSTRIAL ORGANIZATIONS with many workmen may find useful an illustrated pamphlet on *Change Houses in the Lake Superior Region*, by Cleve E. Kendall, Mine Car Surgeon, U. S. Public Health Service. (One copy to a person free while they last from U. S. Bureau of Mines; 15c. from Superintendent of Documents, Washington, D. C.)

STANLEY PINEL has written and the Engineering Extension Department, Iowa State College at Ames, has published a 38-p. illustrated pamphlet on *The Operation and Care of Sewage-Treatment Plants*.

METER INSTALLATIONS AND METER RATES is the title of a short paper by E. I. Roberts, assistant engineer, Ohio Department of Health, Columbus, Ohio, published by the department. The paper is a response to a demand for information from officials of Ohio municipalities "brought about by the increased cost in the operation of waterworks." Diagrams are included.

SMOKE ABATEMENT—domestic, industrial and locomotive—is reviewed by Osborn Monnett in a bulletin issued by the U. S. Bureau of Mines. There is a section on city smoke ordinances. (Washington; one copy free from the Bureau of Mines; 15c. from Superintendent of Documents, Washington, D. C.)

IN SUPPLEMENT 23 TO THE MONTHLY WEATHER REVIEW, Washington, D. C., Jesus Hernandez, an engineer, takes up the Temperature of Mexico. (Free to U. S. Weather Bureau Co-operators; 10c. from Superintendents of Documents, Washington, D. C.)

New Books and Revised Editions

ELEKTRISCHE TEMPERATURMESSGERÄTE—Von Dr.-Ing. Georg Kelmuth. Munich and Berlin: R. Oldenbourg. Paper; 7 x 16 in.; pp. 275; 219 figures in the text. Paper, \$2.10; cloth, \$2.65 (both in Germany.)

ELECTRO-CHEMISTRY RELATED TO ENGINEERING—By W. R. Cooper, M. Inst. E. E.; Assoc. M. Inst. C. E.; Fellow Inst. Phys. (Edited by Bertram Blount, F.I.C.). New York: D. Van Nostrand Co. Cloth; 6x9 in.; pp. 136; 53 line cuts and half-tones, \$3.75.

Among the chapters there is a long one on Electrical Precipitation of Dust, Smoke and Fume, and there are two short ones on Electrolytic Corrosion by Stray Earth Currents and the Relative Importance of Cheap Power and Cheap Freight.

ELEMENTS OF ENGINEERING THERMODYNAMICS—By James A. Mower, James P. Calderwood and Audrey A. Potter (Second Edition, Revised) New York: John Wiley & Sons. Cloth; 6 x 9 in.; pp. 228; 75 figures. \$2.50 net.

ENGINEERING DRAWING—By H. H. Jordan, Head Department of General Engineering Drawing, University of Illinois; and R. R. Hoelscher, Assistant Professor of General Engineering Drawing, University of Illinois. New York: John Wiley & Sons. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 351; lettering charts, line cuts and half-tones. \$3 (15/-net).

The authors state that they have included these "five kinds of materials" in their book: "(1) Elementary fundamental theories and concepts underlying all forms of Drawing; (2) Illustrations explaining the theory and demonstrating proper modes of execution; (3) complex but related principles; (4) encyclopedic or handbook materials—sometimes called commercial practices; and (5) problems." Principles are laid down and are applied to architectural, structural, map, patent office, and other kinds of drawings. A chapter on the principles of graphic methods is believed by the authors to be new to this kind of a book. Bibliographies are given at the close of the more advanced chapters.

GRAPHICAL ANALYSIS OF STRESSES INVOLVED IN DESIGNING FRAME STRUCTURES: Intended Primarily for Students of Engineering—By William Schubert, Assistant Professor, Department of Civil and Mining Engineering, Michigan College of Mines, Houghton, Mich. Houghton, Mich. Published by the Author. Cloth; 6x9 in.; pp. 139; 99 line cuts and half-tones.

LEHRBUCH DER EISENHÜTTENKUNDE: Verfasst für den Unterricht den Betrieb und das Entwerfen von Eisenhüttenanlagen—von Dr.-Ing. E. H. Bernhard Osann, Professor an der Staatlichen Bergakademie in Clausthal. Geheimer Bergrat. Erster Band: Roheisenherzeugung. Zweite, Neubearbeitete und Erweiterte Auflage. Leipzig: Wilhelm Engelmann. Cloth; 6 x 9 in.; pp. 323; 523 figures in the text.

Revised and much enlarged edition of the volume on Pig Iron Production (the Blast Furnace) of the author's *Treatise on the Metallurgy of Iron*. The first edition was reviewed and highly commended to "every iron and steel producer and metallurgist" by Dr. Richard Mendenhall in these columns, Dec. 16, 1915, p. 1175. The companion volume, on Iron and Steel Making Processes based on Blast Furnace Products, was also favorably noticed by Dr. Mendenhall, Jan. 19, 1922, p. 121.

MACHINE DESIGNING DRAWING ROOM PROBLEMS—By C. D. Albert, M. Inst. C. E., Professor of Machine Design, Cornell University. M. Am. Soc. M. E. New York: John Wiley & Sons. Cloth; 6 x 9 in.; pp. 320; 19 line cuts. \$3. 15s. net.

MUNICIPAL GOVERNMENT AND ADMINISTRATION: VOL. I. GOVERNMENT: VOL. II. ADMINISTRATION—By William Bennett Munro, Ph. D., LL.B., Professor of Municipal Government in Harvard University. New York: The Macmillan Co. Cloth; 6x9 in.; pp. 459 and 517. \$3 per volume.

PONTS ET COMBLES MÉTALLIQUES — Par T. Godard, Ingénieur en Chef de la Construction à la Compagnie du Midi, Professor à L'École Nationale des Ponts et Chaussées. Avec le patronage de la Société des Ingénieurs Civils de France et de la Société d'Encouragement l'Industrie Nationale. (Encyclopédie du Génie Civil et des Travaux Publics). Paris: J.-B. Baillière et Fils. Paper; 6 x 9 in.; pp. 667; half-tones and many line drawings.

PROJECTIVE GEOMETRY, WITH APPLICATIONS TO ENGINEERING—By Peter Rich, Professor of Mathematics, University of Michigan. New York: D. Van Nostrand Co. Cloth; 6 x 9 in.; pp. 98; 74 line cuts. \$2.

PUBLIC SPEAKING FOR BUSINESS MEN—By William G. Hoffman, Associate Professor of Public Speaking, Boston University, College of Business Administration. New York and London: McGraw-Hill Book Co., Cloth; 6 x 8 in.; pp. 300. \$2.50.

STRESSES IN FRAMED STRUCTURES. Compiled by a Staff of Specialists—Editors-in-Chief: George A. Hool, Consulting Engineer, Professor of Structural Engineering, University of Wisconsin; and W. S. Bine, Professor of Structural Engineering, University of Wisconsin. New York: McGraw-Hill Book Co. Cloth; 6 x 9 in.; pp. 620; 485 line cuts. \$5.

TECHNICAL WRITING—By T. A. Rickard, Contributing Editor of *Engineering and Mining Journal-Press*. [Second Edition, Rewritten and Enlarged.] New York: John Wiley & Sons. London: Chapman & Hall, Ltd. Cloth; 6 x 8 in.; pp. 337. \$2 postpaid (10/-net).

The first edition was noticed in these columns May 20, 1920. A portion of the volume has been rewritten. Chapters on the wrong word and on punctuation have been added.

A TRANSITION CURVE—By J. E. Williams, Professor of Mathematics, and R. H. H. Beggs, Professor of Civil Engineering, Virginia Polytechnic Institute. [Bulletin No. 1 of Engineering Experiment Station, Blacksburg, Va.] Paper; 6 x 9 in.; pp. 36; illustrated.

The "Lemniscate" curve is the particular form of transition dealt with in this pamphlet, and the treatment is an enlargement of an article by Professor Williams in *Engineering News-Record* of Aug. 26, 1920, p. 466.

WEATHER PROVERBS AND PARADOXES—By W. J. Humphreys, Ph. D., Meteorological Physicist, U. S. Weather Bureau. Author of "Physics of the Air." Baltimore: Williams & Wilkins Co. Cloth; 5 x 8 in.; pp. 125; 18 half-tones and line cuts. \$3 in United States, Canada, Cuba, Mexico; \$3.50 elsewhere.

Cites many folk-sayings, mostly in rhyme, about the sun, moon, stars, fog and clouds in relation to the weather and explains their scientific basis in easily understood language. Paradoxes are likewise explained. Contains good half-tones pertinent to the text including rainbow and cloud effects.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Constructing Engineer on Apishapa Dam Failure

Sir—Since I served, from Aug. 30, 1918, to Sept. 18, 1920, as engineer in charge for the Apishapa Consolidated Irrigation Co. of Fowler, Colo., owner of Apishapa dam which recently failed, and since I also was inspecting engineer for the state engineer, A. J. McCune, who was also actively the consulting engineer to the said company throughout that part of construction subsequent to my employment, I take it that information which I have to give will be of interest to the profession.

The plans prepared by the writer were, with the exception of the plans for outlet works and steel cutoff wall with its various appurtenances, and the rock-fill toe of embankment, merely filed with the state engineer as a record of the changes made in previous plans, so that the plans on file would correspond with the dam as built. Unfortunately, the writer was not permitted to work out such plans for the embankment as he believed were necessary, for the reason that two former sets of plans, already approved, laid down lines which the company and state engineer believed adequate, and the writer was unable to persuade any of the parties concerned that important increases in crest dimensions and slopes were advisable.

I assume that it is not necessary for me to repeat a description of the "phenomena" attending failure of the dam, since these have, as I believe, been clearly and fairly set forth in the report of Floyd and Jones in your issue of Sept. 13, p. 422. I ask you to publish the enclosed photograph, which shows the stationing of the dam, and the elevation at which water issued at time of failure. The point seems to be considerably lower than stated in all reports heretofore. Stationing of the crack across the dam

can also be followed, and anyone interested in speculating upon the relation of settlement cracks to the deeper portions of the fill can do so from this photograph and the plan of the dam in your Sept. 13, issue.

I would like to deal at length with the "causes" of the failure but to touch upon all the causes which contributed to this failure would require so much space that I will limit myself to the following summary: (1) The design of the embankment was inadequate for a dam at the location chosen; (2) the company's financial program was inadequate, and had a vital bearing upon the contractor's methods, and the engineer's power to rigidly enforce the contract; (3) the engineer's specifications were tampered with by a board of directors which, although it contained two "graduate" engineers, did not realize the fact that the utmost care was required to build a dam that would be safe; (4) the contractor after the company had defaulted financially, felt compelled to take the work into his own hands and complete it so as to save himself financial loss; (5) the writer, throughout his connection with the job, was practically the only one who insisted upon the use of thorough construction methods, and was not sustained in his contentions by the state engineer, and but for the writer's insistence, the dam would have been built without either sprinkling or rolling; and (6) had the writer's recommendations been put into effect, the dam would have had a much wider top and heavier section, and would have been constructed of materials all from the canyon bottom—none from the hilltop—and all layers 6 in. instead of 12 in. thick. There would have been no omitted rock-fill toe—no unlined tunnel—and far less of settlement cracks. The dam should have been constructed so that settlement could not have amounted to much, and here was fundamentally where the writer differed with the state engineer and the company officials, and its two "engineer" directors, all of whom contended that "settlement, even if it did occur, would not be a serious matter."

Throughout the construction of the dam, the writer was forced to fight for the incorporation of features of design which he felt were in accord with sound engineering practice, and without which the dam could not be made safe. It was a losing fight. Had it not been for his efforts, Apishapa dam would have been even more unstable than it

proved to be. Had his ideas prevailed, the dam would have had a better chance, at least, of being in place today.

Having in all ways tried to bring about the construction of this dam along safe lines, and, failing in this, having warned the proper authorities of the danger attached to improper use of the, as yet, uncompleted structure, the writer thinks he discharged every duty that could reasonably be expected of him—even to “running the level” Mr. Fellows mentioned on p. 776 of your issue of Nov. 8.

In closing, I wish to say that failure of this dam was due to inadequate design, inadequate financial program, improper construction methods, use of material other than that specified and last, but certainly not least, *improper use of a reservoir the dam of which was known to be unsafe for storage to high water line.* A written order and a padlock could have prevented the whole disaster. Reasonable use of the reservoir might have been ordered until proper increases in section, and studies of incipient failure, were made.

As to the character of material complained of by Messrs. Field and Fellows, I am content to ask these gentlemen to read, on p. 53 of their 1911 report, the excerpt that follows, and then tell the profession what magic change took place in these materials between 1911 and 1923 that rendered the materials, formerly “good” to be now “unsuitable”:

“There is a large amount of soil in the canyon both above and below the dam, *suitable for an earth embankment.* There is also *good dam material* on the high ground to the east of the canyon, and in the reservoir basin itself, so that there is an abundance of material comparatively handy and *suitable in character.*” [Italics mine.] The materials actually used in the dam came from points which they have above described.

CLAIR V. MANN.

Rolla, Mo., Nov. 15, 1923.

Why the Garden City Project Failed

Sir—Referring to the letter of George S. Knapp, State Irrigation Commissioner, regarding the Garden City, Kan., reclamation project (*Engineering News-Record*, Dec. 6, 1923, p. 943), the outstanding thing is the apparent lack of a full comprehension of the original intent and scope of the Reclamation Act under which this project was built.

When the law was discussed and passed it was for the purpose of authorizing the Secretary of the Interior to build, operate and maintain certain large works described in Congressional debates as reservoir and main line canals, leaving to the entrymen or landowner the task of distributing the water. The law was also very carefully guarded against committing the government in advance to any cost, and provided in express terms that the cost should be announced by the Secretary after the contracts were let. This was because much of this work was known to be experimental and the Congress was not willing that the Secretary of the Interior should be put in the position of a contractor guaranteeing any specific statements as regards cost or quantity of water to be delivered.

Each Secretary concerned issued drastic orders to the effect that no preliminary estimates could or should be considered as binding and in all cases care was taken to show that any such statement of possible or probable cost of any particular piece of work had no binding effect and could not, until the contracts were let and the Secretary had taken formal action. This has been sustained by the courts who have called attention to the intent of the law and to the care taken by all responsible parties from the Secretary down, to assure each one interested that the preliminary statements were what they purported to be and could not be construed as binding.

The Reclamation Act also provided that work should be begun in each of the states named, among them Kansas. Field examinations had been made in that state for many years and carefully conducted efforts to ascertain the location of a feasible project. Public opinion demanded that some of the Reclamation Fund be expended in Kansas. There was also a widespread belief that the so-called underflow would furnish vast volumes of water. Investigations were made of the rate of flow of water percolating underground and although there were reasonable doubts as to the

practicability of bringing this water to the surface in large quantities yet no engineer at that time had sufficiently complete information to be able to withstand the overwhelming popular pressure for a large demonstration of the feasibility of pumping water from this supposedly great underground reservoir. Moreover this question of cost was met by the invariable reply, “We do not care what the water may cost; \$100 an acre would be cheap if we can get it.”

Under these conditions the Secretary of the Interior, yielding to the insistent demand from all sides, ordered that a large demonstration pumping plant be built. He did not obligate himself to furnish any specific quantity of water or at any specified amount of money. He expressly forbade any advance estimates to be considered other than what they purported to be, namely, statements as to the probable cost of the specific works to be built. This was as far as he could go under the law and as far as he would authorize his engineers to proceed.

Remember at all times that the Reclamation Service so-called has practically no legal existence. It is simply a body of men created by the Secretary of the Interior acting under his orders to carry out the intent of the law. These men cannot proceed a step beyond the express authority of the Secretary. He may ask them for opinions and estimates and he may order them to carry out certain work but they cannot in any way obligate him nor can they bind him by stating informally what in their opinion certain works may cost.

In other words, the Garden City pumping project was carefully planned to ascertain whether water could be pumped in a large scale from underground. It was known that it could be had in quantities practically inexhaustible to the pumps then used but until a series of these was located across the valley the limitations of supply could not be determined.

Had the country been more nearly arid, as for example in portions of California, such a pumping plant might have been highly advantageous but under the conditions which then prevailed in western Kansas the work, although well planned according to the engineering information then available, and carried out well within the estimates of the engineers, was not successful, although it is quite probable that had an equal number of wells been more widely distributed and located within an irrigable tract, reached directly from the wells, the enterprise might have been successful. It is easy to look back and tell what might have been done but looking in the other direction with full knowledge of the law and the attitude of the public, it was obviously impossible for any Secretary of the Interior to have refused to carry out the demand for a pumping plant in the Arkansas Valley.

F. H. NEWELL,

Formerly Director, U. S. Reclamation Service.
Washington, D. C., Dec. 1, 1923.

Creosoting Practice on Indian Railways

Sir—I have read with interest on page 857 in the May 17, 1923, issue of your valued publication an editorial entitled “Courageous Pioneering” which deals with the treatment of ties with a mixture of 30 per cent creosote and 70 per cent fuel oil. It may interest your readers to know that about 10 years ago we started experiments by treating sleepers with 50 per cent fuel oil and 50 per cent creosote, which so far have given very fair results.

Some of the Indian railways have been so impressed by these experiments that they have erected pressure-treating plants to treat railway ties with varying percentages of creosote and fuel oil. As an example I may cite the North Western Ry., which has the longest railway system in India. This road is treating pine and fir sleepers with 75 per cent creosote and 25 per cent fuel oil. The Assam Ry. has also just erected a plant and is considering using as little as 33 per cent creosote and 67 per cent oil. The experiments carried out to date lead one to believe that equal proportions of the two oils will preserve the timber beyond the period when such sleepers will have to be rejected for mechanical defects.

Dehra Dun, India, Nov. 6, 1923. RALPH S. PEARSON,
Forest Economist, Forest Research Institute.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Zoning in the West Philadelphia section of Philadelphia has been postponed by the City Council until after Jan. 1, when there will be a change in administration. It is hoped that conflicting interests, in and out of the Council, can then be harmonized.

The Board of Water Commissioners of the city of Detroit has issued formal invitations to the placing in operation Dec. 22 of the new filtration plant. Admission is by ticket. This 320-mgd. plant, the largest of its kind in the world, was described in *Engineering News-Record*, May 17, p. 860.

The Saranac Co. of Plattsburg Has made application to the New York State Public Service Commission for authority to acquire and own the capital stock of the Saranac River Power Corp., a corporation which is now building a new power plant and dam about four miles west of Plattsburg, N. Y.

Contract for the Construction of a 60,000-hp. hydro-electric development on the Ottawa River at Bryson, Quebec, has been awarded by the Ottawa River Power Co., to Fraser, Bruce, Ltd., engineers, Montreal. The total expenditure on this work will be approximately \$3,000,000, and it is expected to have the first unit installed by Dec. 1, 1924.

Electrification of the London Suburban lines of the Southern Ry., England, is to be extended materially, according to plans recently approved by the company. At present there is electric operation on 85 route miles with 248 miles of track, but by the end of 1925 these figures will be increased to 145 and 358 miles, respectively. This work is estimated to cost \$26,000,000.

Nine-Mile Bridge, a Dangerous highway crossing over the New York Central R.R. between Schenectady and Amsterdam, is to be replaced by a new bridge at a more advantageous location, east of the present bridge. This change is the result of an agreement between the railroad company and the New York Bureau of Highways. The estimated cost of the work is \$141,000, which cost will be divided between the railroad company and the state.

In Order to Increase the Low Flow capacity of the Ontario hydro-electric plant at Cameron Falls on the Nipigon River, in northern Ontario, the engineers of the commission are studying the possibilities of diverting the waters of Long Lake, a 50-mile long lake just over the height of land from the Lake Nipigon drainage area, from its present drainage north to Hudson Bay, into Lake Nipigon. The peculiar formation of the land between the two drainage areas makes such a proposition possible.

Proposed Anti-Oil Pollution Bills Before Congress

Bills have been introduced in each House of Congress providing that it is to be unlawful to pollute any of the navigable waters of the United States with oil or other refuse other than sewage from streets, sewers or vessels. Violations are made punishable by fine not exceeding \$1,500 nor less than \$500, or by imprisonment for not less than thirty days, nor more than one year.

Engineers Again To Discuss Department of Public Works

In connection with the annual meeting of the Federated American Engineering Societies to be held in Washington Jan. 10-11, a special meeting will be held on Jan. 9 to forward the formation of a Department of Public Works under the Department of the Interior. This meeting will be called the National Conference on Public Works and will be attended by engineers and architects, instructors, manufacturers, chemists, geologists, economists, and business men from all over the country. Local committees of the old National Public Works Department Association will be revived for the period prior to the meeting.

It is the intention, it is announced, of those who are calling the meeting to recommend the adoption by Congress of a bill embodying that part of the Brown plan of government reorganization which provides for the reorganization of the Department of the Interior, so that that department has two divisions, one of which will be devoted to public works and will include all the engineering activities of the government.

A.G.C. Ballots for Officers

Official ballots have been sent members of the Associated General Contractors of America, election for officers to be announced after ballots have been canvassed Dec. 31.

The list of names on the official ballot follows:

For president (to serve one year)—F. L. Cranford, president, Frederick L. Cranford, Inc., Brooklyn, N. Y.; vice-president-at-large (to serve one year)—A. S. Downey, (partner) A. W. Quist Co., Seattle, Wash.; vice-presidents (to serve until 1927) Zone 1—Leonard C. Wason, Aberthaw Construction Co., Boston, Mass.; Zone 2—H. H. Wilson, Winston & Co., Harrisburg, Pa.; H. R. Blagg, H. R. Blagg Co., Dayton, Ohio; directors (to serve until 1927); Districts 2 and 3—W. A. Rowan, James Stewart Co., New York City; District 7—T. J. Baker, Coddington Engineering Co., Milwaukee, Wis.; L. D. Townsend, Townsend, Shuttleworth, Ballmer Co., Lansing, Mich.; District 8—Henry Ericsson, Henry Ericsson Co., Chicago, Ill.; District 13—Natt MacDougall, A. Guthrie & Co., Portland, Ore.; Districts 14 and 15—H. W. Baum, H. W. Baum & Co., Salt Lake City, Utah.

Width and Thickness To Be Added to California Roads

Contracts to the total value of \$5,000,000 will be made within the next few months, according to a statement made recently by R. M. Morton, state highway engineer, for widening and thickening existing paved routes on California's highway system. Plans and specifications for this work, which includes stretches of road in many parts of the state, are now in course of preparation and in some cases bids have already been called for. This expenditure will be made from funds derived from the state's share of the new gasoline tax and motor vehicle license fees and is in addition to money available from state highway bond funds. It is estimated that this new source of revenue for highway maintenance will be at least \$7,500,000 for 1924, which is 50 per cent in excess of the present revenues for maintenance and reconstruction. The highway commission is to receive its first allotment from the gasoline tax in May, 1924.

Surveys and plans are also under way for considerable construction work on main trunk lines, which is classed as primary construction, and is paid for from bond issues. This work is kept separate from that classed as maintenance and rebuilding, for which the gasoline tax is specifically reserved by law. Primary construction to be undertaken soon includes the paving of 9.9 miles of the highway immediately north of Redding, grading a number of units on the Truckee River route between Auburn and the Nevada state line; work on the Redwood highway north of Eureka to make a connection with the Oregon state highway to Grants Pass, and connections with Yuma, Ariz., in southern California.

Commerce Commission Reverses Decision Against Coal Road

The Interstate Commerce Commission has reversed its decision of June 25 against permitting the Virginian Ry. Co. to build a 1.19-mile extension of its Guyandot River branch in Wyoming County, West Va. into new coal mines. The former decision was based on the claim that the applicant railway was unable to supply cars for the mines now served by it. The Commission also stated that there were more mines open than were necessary for the country's demand and the efficient use of the carriers equipment.

The reason for the reversal is based on the fact that the applicant company has made large increases in its equipment and also plans to increase its capacity by electrification. Moreover the Commission holds that to deprive the coal company of the opportunity to develop these fields would cause it to lose the value of large expenditures which it has made. It also finds that the coal to be mined is Pocahontas smokeless coal, which is in demand on account of its special properties.

Engineers Urged to Take Greater Interest in Civic Affairs

Washington Correspondence

Twice within a week assemblies of engineers in Washington were urged to advocate greater political activity on the part of their members. The first instance was at the convention of the chemical engineers. One speaker asserted that of all the chemical engineers in attendance at the convention, only one had been particularly active in politics.

The other admonition along this line came from President Loweth, of the American Society of Civil Engineers. In an address Dec. 11, before the Washington Section of the Society, he stressed the need for greater attention to public affairs on the part of engineers individually and collectively.

No other profession is as well paid by the communities they serve than is the engineer, Mr. Loweth said. He admitted that the lawyers might contest the statement, but if the earnings of that profession were stripped of profits from real estate and other outside activities, it would be found that their earnings for strictly legal work would show a lower aggregate than that of the engineering profession. Were engineers to take a larger interest in civic matters, even greater returns would come to the profession, but above and beyond the matter of increased earnings, the engineer, he believes, has a duty as a citizen.

Referring to the removal of A. P. Davis from the Reclamation Service, Mr. Loweth said this injustice to an engineer should not discourage engineers from giving service. Very frequently, he said, service is not rewarded as it should be, but the obligation to perform it remains nevertheless.

Reclamation Finances Tabulated

A tabulation of cost, repayments, water charges, and similar data for the various projects in the U. S. Reclamation has been prepared in the Department of Interior for the use of the Committee of Special Advisors on Reclamation. The tabulation is reproduced substantially complete herewith. It includes the Buford-Trenton, Hondo, and Garden City projects that have been abandoned by the government, and the Riverton project, yet under construction. It is to be understood that the figures given as originally

estimated cost did not contemplate supplemental construction, such as subsequently entered into the actual cost. Included in the cost of construction, further, is a total of \$12,922,455, representing the cost of furnishing water under the Warren Act and other special contracts. The construction cost figures also include arrears in payment for water charges that have been transferred to construction by act of Congress or departmental order. The water charges given in the table include an item of \$1,059,864 representing the cost for the first six months of 1923, for which no assessments have yet been made. The acreages do not include areas to which water is furnished under the Warren Act or other special contracts.

Three projects, Grand Valley, King Hill, and Milk River have not yet been opened by public notice and water is being sold on a rental basis. The Salt River acreage includes some area taken in by the Salt River Valley Water Users Association, on which the association spent additional money for construction. The cost of the Yakima project includes \$2,515,875.62 expenditure on the Rimrock dam, which is expected to bring additional acreage under irrigation.

In a statement accompanying the tabulation the following remark is attributed to Secretary of the Interior Work: "The Reclamation Service of the government has had but two directors in its history of twenty-one years, both engineers and each with ten years' service. They have erected their own monuments and the different projects are writing the inscriptions for them."

Yuma Flood Protection Bill Before Congress

Protection against the Colorado River flood danger at Yuma, Ariz., would be assumed by the United States Government under a bill just introduced in Congress by Senator Ashurst, of that state. The bill provides an annual appropriation of \$100,000 for such work, and a single appropriation of \$100,000 to refund past expenditures on flood fighting, which heretofore has been charged against the Yuma irrigation project as part of operation and maintenance. The bill also declares it to be the policy of the United States to assume the obligation of caring for the river-front work and levee system on the Yuma project.

Two Power Developments Proposed For the Upper Delaware

The Shohola Water Power Co., the Bingham Water Power Co., and the Blooming Grove Water Power Co., have declared their intention jointly to construct two power plants on Shohola Creek, a tributary of the Delaware River, in northeastern Pennsylvania. They propose to construct a 60-ft. dam at the head of Shohola Falls and run a pipe line to a point downstream where they can develop a head of 270 ft., at which point they will construct a power house with two 4,000-hp. units. A second dam is being constructed at Cold Spring Lake and a second pipe line to a power house, where a head of 290 ft. will be developed and three 4,500-hp. units installed. As the project calls for a storage of 2,500,000,000 cu.ft. of water, it is probable that the Federal Power Commission will take jurisdiction over it on account of its effect upon the flow in the Delaware River.

Reject River Diversion Project

The engineering staff of the Federal Power Commission has advised the Newman-Hirstel interests of San Francisco that it will recommend the rejection of their application for a preliminary permit to develop power by the diversion of the San Benito River from its natural course into the San Joaquin River. Investigations of the engineering staff have revealed that all the water of the San Benito is needed for irrigation. Moreover, the staff believes that the development of the river in its natural course is more promising and less expensive than the proposed diversion. The diversion would have the effect of lowering the level of ground water at points below the point of divergence and would almost certainly result in extensive litigation over damages.

Testing Materials Again Will Meet in Atlantic City

Announcement has been made by the executive committee of the American Society for Testing Materials that that society's annual meeting will be held at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., Monday, June 23, to Friday, June 27, or Saturday, June 28, 1924.

[illegible]

TABULATION OF COST, REPAYMENTS, WATER CHARGES, ETC., ON RECLAMATION PROJECTS

New Jersey to Bring Suit Against Federal Power Commission

Washington Correspondence

In an action similar to that taken by the state of New York against the Federal Power Commission, the state of New Jersey has now entered a motion for leave to bring suit against the commission to enjoin it from acting in that state "by an abuse of power without lawful and constitutional authority or in pursuance of wrongful and erroneous interpretations of the provisions" of the federal water power act, which act the state will ask the U. S. Supreme Court to declare unconstitutional.

The principal complaint of New Jersey is that the Federal Power Commission is attempting to exercise jurisdiction over the state's proposed development of water power along the Morris Canal. This canal, which runs from the Delaware River at Phillipsburg, N. J. to the Hudson River at Jersey City, was started in 1824, passed through various hands until it eventually came into the hands of the Lehigh Valley Ry. Co., and last year was purchased by the state of New Jersey. As the canal has ceased to be of value as a means of transportation the state proposes to use it to develop hydro-electric power by the construction of some new dams, including one on Lake Hopatcong. The state also proposes to develop power above Saxton Falls on the Musconetcong River and at various sites on the Delaware River. The motion cites that the state has not applied to the Federal Power Commission for permit for this work and does not propose to do so. The state also objects to the Commission's asserting authority over riparian land, which land brings in revenue to the state for its school funds, and to the Commission's interference with the conservation policy of the state in connection with its potable water on account of the possibility of its causing heavy losses in investments in waterworks. The state also challenges the Commission's right to regulate rates for the sale of electric power within the state.

Consulting Engineers Urge Tax Reduction

The tax reduction program proposed by Secretary of the Treasury Mellon was recently endorsed at a meeting of the American Institute of Consulting Engineers in New York City. The Institute, believing that a return to country-wide construction program in the industrial and railroad fields is possible only through restoration of public confidence by a reduction of federal taxes, addressed a letter recently to President Coolidge embodying the hope that the President would urge upon Congress the necessity of reducing taxes.

The subject of the tax reduction was taken up at the latest meeting of the Council of the consulting engineers, a resolution endorsing Mr. Mellon's program without qualification being unanimously adopted. The executive officers of the Institute were, therefore, directed to convey that expression to the Secretary of the Treasury and the chairmen of the appropriate committees of both the Senate and the House of Representatives, in addition to communicating directly with President Coolidge.

Corporate Management Suggested for Federal Barge Service

Washington Correspondence

Corporate management for the Mississippi-Warrior barge service has been suggested to the Secretary of War, and legislation to that end is to be introduced promptly. By the formation of a corporation, which will function under the Secretary of War, it is believed that most of the handicaps of government operation can be avoided, and a greater degree of flexibility injected into the administration of the service. The immediate direction of the service would remain in the hands of Col. Ashburn, the plan contemplates, who is to be released for the provisions of the Manchú law, and advanced to the rank of brigadier-general.

At the public hearing at which this plan was explained to Secretary Weeks, that official asked why the operation of the barge line should not be transferred to the Department of Commerce. Secretary Weeks made the point that something must be done to reduce the non-military functions which are being thrust upon the War Department. This led Senator Reed, of Pennsylvania, to inquire if it is proposed to transfer the Corps of Engineers to the Department of Commerce. He said he could not imagine a railroad having its operating division in one department and its maintenance-of-way in another. The suggested transfer was opposed also by Senator Brookhart, of Iowa; Senator Reed, of Missouri, and Senator Broussard, of Louisiana.

The corporation which is proposed is to be the recipient of the proceeds of a bond issue, which may not exceed \$10,000,000. The money is to be used for the purchase of equipment, the construction and maintenance of terminals, and as a revolving fund.

Civil Engineers Appointed on Education Committee

President Loweth, of the American Society of Civil Engineers, has been appointed as counselors representing the society on the board of investigation and co-ordination of the Society for the Promotion of Engineering Education, F. C. Shenehon, of Chicago, and J. Waldo Smith, of New York. This board is to study the whole subject of engineering education under a grant of \$108,000 from the Carnegie Foundation, as announced in these columns some weeks ago.

Tacoma Revives Lake Cushman Power Project

The construction of the first unit of the Lake Cushman power project proposed by the city of Tacoma, Wash., is provided for in ordinances for the issuance of bonds and letting contracts introduced in the City Council. The ordinance, passed nearly three years ago, which provided for the development of the project must be amended to suit changes in the plan, and a new ordinance providing for \$4,000,000 of light utility bonds is expected to be passed in time for a call for bids some time in the near future.

The Lake Cushman project called for an ultimate development of 140,000 hp. and an expenditure of \$10,000,000. The first unit will develop 50,000 hp.

To Measure Water Diverted for New York Barge Canal

Measurement of the water passing through the New York barge canal is to be undertaken to determine whether water in excess of the amount needed for navigation is being diverted from the Niagara River. The work will be done by the measuring commission, recently appointed to represent the United States and Canada, the American member being Major F. S. Reinicke, district engineer in charge at Buffalo. W. M. Stewart represents Canada.

It is contended by representatives of the federal government that no water is being diverted through the canal over and above the requirements for navigation, although in issuing a license to the Niagara Falls Power Co. it was assumed that 500 sec.-ft. of treaty water was going through the canal. Certain interests in Lockport and Medina have laid claim to the right to use this 500 sec.-ft. and have applied to the Federal Power Commission for a license to cover its use. Those interests hold a revokable state permit which recites their right to have this amount of treaty water transported through the canal as far as Lockport.

If it is found that no treaty water is being transported through the canal, it is assumed that the Federal Power Commission will license the 500 sec.-ft. for diversion at the Falls. Even in that event it is understood that the Niagara Falls Power Co. is willing to remunerate the holder of the state license for any equity which he may possess.

Trucks to Replace Way-Freight on P. R.R. Branch

Motor trucks have taken so much of the L. & L. freight business in some thickly settled regions that the operation of such freight trains is no longer economical. To overcome this the Pennsylvania R.R. has announced that it will abandon this part of its way-freight service between Wilmington and Philadelphia, and has entered into an arrangement with a trucking organization for the required motor truck service in the territory affected. The railroad company's statement says that the new plan has enabled it to dispense with two freight trains daily, one in each direction. Two motor trucks are now doing the work of these trains with greater efficiency due to their flexibility and greater speed in movement. The new arrangement does not involve any changes in rates.

Cherokee Bluffs Power Project Well Under Way

Work on the new 132,000-hp. hydro-electric development of the Alabama Power Co. at Cherokee Bluffs on the Tallapoosa River is well under way. Four of the six miles of railroad which the company is building to the power site have been graded and track has been laid for three miles. The high-tension transmission line bringing power to the site has been completed and a 460-ft. section of the cofferdam in the river is ready to be unwatered.

The total head to be developed at this site will probably be increased from 120 ft. to 150 ft. for storage purposes. The first installation will be 43,000 hp.

Municipal Toll Bridge Over Ohio Proposed for Louisville

A report on the project for a new highway bridge over the Ohio River at Louisville has just been made by the bridge committee of the Louisville Board of Trade, embodying the specially interesting feature of a municipal toll-bridge plan. The report asserts the principle that those who use the bridge should pay the main part of its construction cost. It recommends locating the bridge at 10th St., connecting with Warner Ave. in Jeffersonville. The cost of the bridge is estimated at \$4,790,000, or, with interest and contingencies, something over \$5,000,000. The toll income that might be expected immediately after completion is estimated at \$350,000 per year, which would assure a sufficient balance over fixed charges to provide for amortization.

Preliminary plans included in the report to the Louisville Board of Trade made by Fay, Spofford & Thorndike, consulting engineers, call for a structure of 17 steel spans carrying a concrete deck supporting a bituminous wearing surface. The sidewalk will be of concrete and concrete railings will be used. Excluding the approaches, the bridge will contain the seventeen 206-ft. spans and one 410-ft. span across the canal, and a 650-ft. span across the river channel. The total length of this portion of the bridge, which is practically level, is 4,663 ft.

The location of the bridge is about 1,500 ft. upstream from the Pennsylvania R.R. bridge, which it resembles in a general way. The roadway of the bridge will be 40 ft. wide with a 6-ft. sidewalk on the upstream side.

Regional Planning for Chicago 50-Mile District

The Chicago Regional Planning Association, organized Nov. 2 at the second conference on regional planning, is to serve the territory within fifty miles radius from the center of the city. This territory comprises what may be termed the Chicago industrial district and the purpose of the new association is to study conditions and promote co-operation in both industrial and social development, so that, for example, when a new industry is to be established the question of adequate local transportation, sanitary and housing conditions will not be overlooked.

Definite lines of activity by the association are to include the following: (1) A physical survey of topographical conditions, transportation, population and public utilities; (2) an industrial and commercial survey; (3) a health and housing survey as to water supply, drainage, sewerage, zoning regulations and housing conditions; (4) an educational survey of schools, parks, bathing beaches, forest preserves areas and commercial recreation facilities; (5) a governmental survey of the various governmental organizations within the region and a study of legislation.

The meeting elected Dwight H. Perkins as the first president. Three classes of membership are provided in the new constitution: individual, contributing and organization members, the last including county and municipal bodies and civic or community associations.

Retention of Construction Road Raises Common-Carrier Issue

Washington Correspondence

The application of the Portland Railway, Light & Power Co. for an amendment to its license which would allow it to retain the railroad which it built to its power development on the Clackamas River, 50 miles south of Portland, as a permanent adjunct to the development to insure the ready transfer of heavy machinery to the plant in case of accident, has raised the question as to whether such a permit should not require the operation of the road as a common carrier. The power project occupies a site in a very inaccessible part of the undeveloped forest area. The original plan called for the construction of a railroad to a point about 6 miles above the existing terminal at the company's Cazadero plant and the use of a wagon road for the remaining 20 miles. During construction, however, the company found it necessary to build the railroad all the way to the plant. This was done with the permission of local forest officials. These officials now object to the company retaining this railroad for emergency purposes unless it be operated as a common carrier. The power company has agreed to handle such shipments of forest products as are offered to it, but the Forest Service holds that the presence of the railroad along the only location suitable for a wagon road precludes the use of that location as a wagon road, and necessitates the operation of the railroad as a common carrier or else the removal of its rails.

Tramway and Light Railway Society to Meet at Paris

The International Congress of Tramways, Light Railways and Omnibuses will hold its next meeting at Paris in 1924. A preliminary list of subjects includes the following: (1) Improvements in track design and electric and mechanical operation of switches; (2) improvements in car design; motors and electrical equipment; loose wheels; radial axles; reduction in weight; brakes; (3) use of automobiles on rails; (4) transportation facilities in relation to the extension of towns and suburban districts; (5) employment and periodical examination of employees; (6) improvements in locomotives for light railways; fuel economy due to superheaters, feed-water heaters and other appliances; (7) motors for buses.

Largest Hydraulic Turbine Put in Operation

The first of three 70,000-hp. single-runner, vertical-shaft hydraulic turbines of the Niagara Falls Power Company's new plant in the Lower Gorge was put into service on Dec. 18. The new unit uses a flow of 3,200 sec.-ft., the amount now used by seven 5,000-hp. units in the old plant, with twice the output of that plant without any increase in the amount of water diverted from the Falls.

The runner is a single piece of cast steel weighing 105,000 lb. with the 32-in. shaft and the 399-ton rotor of the generator, make up the revolving element of approximately 500 tons weight suspended from the top of the unit by a Kingsbury thrust bearing.

Random Lines

Another Argument Gone

In New York the other day a prominent lawyer resigned from the Bar Association because lawyers do not "take enough interest in public affairs." Thus is shattered our fondest illusion and most potent argument for the bettering of the engineering profession. How are we going to argue for a more active participation in community life by the engineer if we cannot point dramatically to our lawyer-ridden government and the precedent lawyer-interest in public affairs.

False Pretenses

Some of the things in this column are meant to be funny. This item is not.

The following advertisement has been running for some time in a New York newspaper:

YOU CAN BE A DRAUGHTSMAN

Mechanical or Architectural A Profession Not Overcrowded

Few months' spare time training under direct supervision of experts, which will not interfere with your present duties will qualify you in this well-paying profession. Draughtsmen earn \$5,000 to \$25,000 yearly. Let us show you how you can prepare for one of the many positions now open.

METROPOLITAN INST. OF DRAFTING

154 Nassau Street.

Suite 610

It is hereby respectfully called to the attention of the postal authorities.

* * *

A Brutus Stroke

It looks as though we are going backward in our campaign against adjectival engineers. We are being attacked in the house of our friends. First comes the New York Section of the American Institute of Electrical Engineers with a program which announces a discussion on "human engineering" and a plea for intensive work in "membership engineering." And then the American Engineering Standards Committee sends a circular in which we are assured that "standardization engineering" is now a recognized profession in Germany and that advertisements for "standardization engineers" appear regularly in the engineering press. The morale of the technical press in Germany has probably suffered with everything else there. There isn't much they won't do for real money. But why countenance the debasing of the honest word "engineering" in 'his country? The Standards Committee finds, too, that "another most interesting development is the work of consulting engineers on trade catalogs." Add then to the immortals — "trade catalog engineers."

Engineering Societies

Calendar

Annual Meetings

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.; Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-24, 1924.

ENGINEERING INSTITUTE OF CANADA, Montreal; Annual Meeting, Montreal, Jan. 22, and Ottawa, Jan. 23, 24, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich.; Annual Meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, Chicago, Ill.; Annual Meeting, Chicago, March 13-15, 1924.

The North Carolina Section of the American Water Works Association at its recent meeting in New Bern, N. C., elected the following officers: President, J. C. Michie, superintendent of the Durham, N. C., water-works; vice-president, William H. Piatt, construction engineer, Durham; secretary-treasurer, Thordike Saville, Chapel Hill.

Personal Notes

F. A. LAMMIMAN, formerly connected with the firm of Polk and Robinson, civil engineers of Chico, Calif., has been named city engineer of Chico, succeeding Frank S. Robinson, resigned.

C. F. PRICE, present city manager of San Mateo, Calif., has been appointed city engineer and superintendent of streets, succeeding G. Stanley Whitehead, who has been city engineer of San Mateo for four years and who recently resigned.

The JASPER-STACY Co., a new construction firm, has opened offices at 216 Pine St., San Francisco, and will engage in construction on irrigation, reclamation, power, factory, building, municipal and other enterprises. The firm is headed by B. P. LILENTHAL, vice-president of the Union Sugar Co. and South San Francisco Land Co. The vice-president is O. W. JASPER, Jr., manager of the Shattuck Construction Co. of San Francisco for the past seven years. The secretary is N. T. STACEY, engineer, whose most recent work involved the expenditure of \$5,000,000 in townsite, railway and factory work.

WILLIAM ARTINGSTALL, consulting engineer, Chicago, has been made consulting engineer to the Department of

Public Works, Chicago, reporting directly to Col. A. A. Sprague, commissioner. His duties include handling the city's supervision of the Illinois Central terminal, Union Station, and other railroad terminals, in addition to all matters coming to the commissioner by special ordinance.

J. E. MOODY, engineer in charge for the city of Chicago on the development of the Illinois Central R.R. terminal, has resigned.

A. J. GOODE has been appointed county engineer of Red River County, Texas, succeeding J. B. Reiman, who has resigned. County engineering headquarters are at Clarksville.

J. P. KEARBY has been appointed county engineer of Fayette County at La Grange, Texas, succeeding CAPT. A. SCHLAFI, who becomes a division engineer for the Texas State Highway Department.

H. G. FLURY and R. A. KIZER have opened an office at 125 Wirthman Bldg., Kansas City, Mo., under the firm name of Flury & Kizer, engineers, for the practice of structural engineering. Mr. Flury was formerly with the Kansas City Terminal Ry., the Kansas City Structural Steel Co. and the Interstate Commerce Commission.

GEN. WILLIAM LUTHER SIBERT has been appointed president and general manager of the Alabama Dock Commission to succeed the retiring temporary commissioner, George Gordon Crawford. Gen. Sibert served as a member of the Isthmian Canal Commission from March, 1907, until April, 1914, and as chairman of the Board of Engineers on the flood prevention work in the Hwai River valley, China. He was promoted to the rank of brigadier general and was extended the thanks of Congress by an act approved March 4, 1915. Shortly after the outbreak of war in 1917 he was promoted to the rank of major general and sent to France with the First Division. Following this he served in the Chemical Warfare Service from May, 1919, until February, 1920.

ARTHUR E. LODER, district engineer of the U. S. Bureau of Public Roads, who has been in charge of federal aid work in the southeastern district of the United States, has been selected as manager of the Good Roads Bureau of the California State Automobile Association, succeeding C. C. Cottrell. Mr. Loder, after graduation from Purdue University, was for some years chief engineer of the Los Angeles Highway Commission and division engineer for the California State Highway Department.

F. D. HUDGINS, state highway engineer of South Dakota, has resigned, effective Jan. 1, 1924. His successor has not yet been appointed.

JAMES F. SANBORN and CLINTON L. BOGERT, consulting engineers, have formed a partnership, with office at 30 Church St., New York City, and are prepared to design, report on and supervise construction of water supplies, sewers and sewage disposal, tunnels, concrete structures and municipal works. Mr. Sanborn, a graduate of Harvard University, was connected with the construction of the Battery tunnel of the New York subway and the northern aqueduct department of the N. Y. Board of Water Supply (Catskill aqueduct). Mr. Bogert, a graduate of

Cornell, has been engineer in the design division of the Board of Water Supply, New York City, on tunnel and reservoir work. He is co-author with Alfred D. Flinn of a handbook of water supply.

R. DE CHARMS, of Oil City, Pa., has been appointed resident engineer on the construction of a highway bridge across the Allegheny River at Oil City, for Venango County. Mr. de Charms was formerly assistant bridge engineer for the New Jersey State Highway Commission, at Newark, N. J.

JOHN A. FOCHT, recently county engineer of Rockwall County at Rockwall, Texas, has been appointed county engineer of Nolan County at Sweetwater. Nolan County has just voted a large bond issue for highway construction. Mr. Focht is an engineering graduate of the University of Texas and was an engineer officer in the late war. Formerly he was city engineer of Sweetwater in charge of extensive water-works and paving improvements.

SAMUEL REA, president of the Pennsylvania Railroad Co., has been elected president of the Long Island Railroad Co., to succeed Ralph Peters, deceased. George Le Boutillier, whose election to the presidency of the Long Island Railroad was announced in error some weeks ago, continues as vice-president of the company in charge of all matters concerning operation.

HUBBELL, HARTGERING & ROTH is the name of a firm of consulting engineers recently organized in Detroit, Mich., and composed of CLARENCE W. HUBBELL, J. MCRAE HARTGERING and ALBERT ROTH. The firm will specialize in water supply, sewerage and municipal engineering. Mr. Hubbell was city engineer of Detroit from 1917 to 1922. The address of the new firm is 2346 Penobscot Bldg., Detroit.

S. L. WONSON, bridge engineer of the Missouri Pacific R.R., has been appointed assistant chief engineer, succeeding the late H. R. Carpenter.

F. E. BATES has been appointed bridge engineer of the Missouri Pacific R.R., succeeding S. L. Wonson promoted to assistant chief engineer.

Obituary

ISAAC WINSTON, hydrographic and geodetic engineer, inspector in charge of the Geodetic Field Station in New York City, died recently in his 71st year. Since 1878 he had been in the service of the United States Coast and Geodetic Survey.

GEORGE E. STEELE, civil engineer, who was prominent in engineering in Wisconsin for many years, died Dec. 6 in Grass Valley, Calif., where he has lived in retirement for two years. He was 81 years old. He located in Los Angeles some years ago and designed the streets and sewer system of the city of Hermosa Beach, Calif. Mr. Steele was a native of Ohio.

LOUIS BACQUE, civil engineer, Newmarket, Ont., died in that city Dec. 9 at the age of 67 years. He was a native of Bordeaux, France, and went to Canada forty years ago, where he practiced civil engineering in Montreal and Toronto. He was an authority on the use of peat for fuel.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Interviews with Industrial Executives—4

Close Contact with Job Aids Design and Operation of Trench Excavators

FROM a heavy, unwieldy steam-driven machine mounted on wood rollers, the trench excavator, in a comparatively short time, has been developed into a compact, mobile, all-steel unit powered by a gasoline engine and operated on crawler treads. Notwithstanding these improvements, the demand for faster-digging machines of greater mobility even now necessitates periodic changes in design to keep the machines abreast of general progress in the construction field. This is a subject to which the Parsons Co., Newton, Iowa, manufacturer of trench excavating and backfilling machinery, attaches great importance. In an interview with *Engineering News-Record's* representative, H. C. McCardell, general manager of the company, stated that it has been the practice of his organization to replace an old design by an entirely new one every five years. This means the introduction of a new ma-

H. C. McCardell, general manager of the Parsons Co., Newton, Ia., explains how ideas from the field are capitalized in improved design and how demonstrators aid contractors in starting work right.

cutting attachment for use on our trenching excavators. The idea was brought back to the factory by one of our operators who was demonstrating a machine for a contractor. The contractor had conceived the idea of this device for increasing the width of cut of the buckets and was experimenting with it on his work. It was something entirely new at that time and when

DEMONSTRATING CORRECT OPERATION OF
TRENCH BACKFILLER

experience indicates will aid him in his work. A case of this sort happened when one of our engineers was visiting a contractor in the Middle West doing work in winter. The ground was frozen and he was using picks to dig ahead of his trenching machine. Our engineer suggested that he pipe his exhaust steam ahead, using a cover of straw or manure to thaw out the ground. The contractor adopted this suggestion and made a substantial saving in time and labor."

Supplementing this policy of continuing improvements in design resulting from job contact, the company's plan of co-operation with contractors includes these additional features: (1) Investigation of local ground conditions before a sale to prevent the use of a trench excavator on work for which it is not adapted; (2) shop and field tests of equipment before shipment; (3) operating instructions on the job by one of the company's demonstrators; (4) detailed printed instructions and blue-

EACH EXCAVATOR IS TESTED AT THE COMPANY'S PLANT (LEFT) BEFORE IT IS ALLOWED TO BEGIN WORK ON THE JOB (RIGHT)

chine each year, as the equipment is made in five standard sizes to meet ordinary demands for ranges of work. These five sizes are designed for trenches having widths of 18, 30, 40, 48, and 78 in.

Close contact with the equipment on the job is the foundation of the Parsons Co.'s service to its customers, which begins with the design of the machine. Through its twenty-nine branch offices and agents in the United States and Canada, regular travel by its sales engineers and special trips by members of its designing staff, operating difficulties under actual working conditions are noted and corrected and improvements in design made.

"This policy of contact with the job," Mr. McCardell explained, "has proved of great value both to our company and to the users of our equipment. A case in point is the development of the side-

our engineering staff received a detailed report on this attachment an improved design was worked out and the device made regular equipment on all of our trench excavators."

On another occasion, Mr. McCardell added, a Parsons salesman was visiting a contractor in Nebraska who was using a backfiller for a trench in a narrow alley—only 16 ft. wide. The backfiller is equipped with a long boom which makes difficult operation in restricted quarters. This contractor, however, had devised an attachment which solved the problem and, with his permission, the company incorporated this feature in subsequent designs of its machine.

"Ours is a policy of give and take," Mr. McCardell continued. "We get many valuable suggestions from the contractor, and, in the same spirit of co-operation, we offer advice which our

prints; and (5) adequate and prompt supply of repair parts even for machines of out-of-date design.

"We never sell a machine to a customer where there is any doubt as to its ability to do the work in a satisfactory and economical manner," said Mr. McCardell. "Where ground conditions are not suitable we advise a customer against using a trench excavator and recommend such other equipment as, in our estimation, is best suited for the work. The pursuit of such a policy, of course, requires competent men in the sales department whose experience and good judgment may be depended upon for a correct recommendation to the prospective buyer. We believe it is good business to think of the ultimate results to be gained by the purchaser rather than the immediate profits to be secured by the company."

A machine is never permitted to leave the company's shops in Iowa until it has been thoroughly inspected and tested. When it reaches the contractor, therefore, it is ready immediately to go to work. The shop inspection concerns itself principally with checking to see that the alignment of working parts is true and that the driving chains run straight. After this examination has been made the excavator is taken out to a 10-acre testing lot behind the company's shops and made to dig a trench of the maximum width and depth for which the machine is designed. On this test all parts are tried up and adjustments made to insure the satisfactory operation not only of the digging buckets but of the cleaner and conveyor.

The company considers it good insurance to have its machines started right on the job. It has been found that the hardest time to satisfy the customer is when the machine is starting its work. For that reason the company sends one of its trained operators—from three to five of these men are regularly employed—to the work where each excavator is shipped. This man supervises the unloading of the machine and instructs the contractor's operator in proper methods of handling it. The company also maintains a list of skilled trenching machine operators from which a man can be supplied to the contractor if desired for permanent employment.

In addition to this personal instruction, the company sends out with each machine detailed printed instructions and blueprints, together with lists of parts, each being illustrated by a photograph and numbered so as to avoid confusion in ordering duplicates.

TO AVOID TROUBLE

As the result of observing the operation of hundreds of trenching machines the company has noted that, where trouble occurs, it can usually be traced to one of the following causes due to neglect on the part of the owner:

- Failure to keep boxes tightened up.
- Loose bolts.
- Gears out of alignment.
- Improper lubrication.
- Neglect of bevel-gear adjustment.
- Use of chains in which links, pins and bushings are worn out.
- Neglect, during the winter, to paint the machine and grease the shafting and gears.
- Allowing the excavator to remain out in the open all winter instead of placing it under cover.

When the company is advised, by the reports of its field representatives, that owners are not maintaining their machines in good operating condition letters are written to them calling attention diplomatically to these shortcomings.

The shop equipment and organization of the Parsons Co. is lined up for rapid production of parts, even those that may be out of style. The policy is to keep on hand a stock of repair parts for all machines that have ever been built by the company. As part of this service the company operates its own electric steel foundry, so that it is possible to make any particular kind of steel needed for different parts of trenching machines. However, customers are advised to maintain on the job an adequate stock of repair parts.

Business Notes

BARBER ASPHALT CO., Philadelphia, announces the opening of a new district office at 807 Phelan Building, San Francisco, in charge of Major C. M. Foster, former representative of the company in Washington, D. C.

CHICAGO PNEUMATIC TOOL CO., New York, announces the General Machinery Company of Spokane, Wash., as its agents in the eastern part of Washington and northern part of Idaho.

SANDUSKY CEMENT CO., Cleveland, Ohio, announces the election of J. B. John as president and general manager. His connections with other companies will remain as formerly.

Receivers of the **SIZER STEEL CORP.**, Buffalo, N. Y., C. B. Porter, John T. Dillon, and Stewart F. Hancock, announce that the manufacture of all kinds, grades and finishes of commercial forgings has been resumed in addition to the company's output of rolled bars, die blocks, oil well steels, and spiral stems.

EASTERN PAVING BRICK MANUFACTURERS ASSOCIATION, at its fifth annual meeting in New York Dec. 11, re-elected the following officers: President, R. L. Winslow; treasurer, R. T. Hutchins; secretary and chief engineer, William C. Perkins.

KETTLE RIVER TREATING CO., Madison, Ill., reports that improvements are being made to the plant recently acquired. About 10 acres of land for storage space have been leased and supplied with tracks, while an additional area is being graded and the entire yard covered with cinders. This plant has equipment for both zinc and creosote treatment and also for adzing and boring ties.

COPPER & BRASS RESEARCH CORP., New York, at its third annual meeting held in New York recently, elected the following officers: President, R. L. Agassiz, Calumet & Hecla Consolidated Copper Co.; vice-presidents, B. F. Kelley, Anaconda Copper Mining Co.; F. S. Chase, Chase Metal Works; Walter Douglas, Phelps Dodge Corp.; H. J. Rowland, Rome Brass & Copper Co., and U. G. Hungerford, Hungerford Brass & Copper Co.; treasurer, Stephen Birch, Kennecott Copper Corp.; secretary, George A. Sloan; manager, William A. Willis.

In designing the different sizes of machines parts are made interchangeable in so far as possible. This is particularly true of sprockets and chains. This policy enables the owner to carry a minimum stock of repair parts and often saves him loss of time due to shutdowns.

A recent improvement has been the use of removable sprocket teeth. In case of a break a single tooth may be taken out and another substituted without removing the sprocket from its shaft. Also, to withstand increased wear, bushings and pins on chains have been made of manganese steel.

"Our whole policy of service," Mr. McCardell concluded, "is built up on the theory that a satisfied customer is our best advertisement."

Equipment and Materials

Inserts in Concrete Carry Angles Supporting Brick Veneer

For anchoring face angles to carry brick veneer in concrete skeleton construction Truscon adjustable pressed steel inserts have been used recently as a substitute for bolts. Where it has been common practice to drill the wooden forms for the insertion of the bolts to carry these face-angles, David J. Johnson, a superintendent of con-

struction in Chicago, devised the new method of construction in a series of six large apartment hotels in Chicago to save money in erection costs. A saving of \$3 per hundred in favor of the insert is claimed. The following unit costs are taken from a study of the contractor's time sheets.

With Bolts	Cents
Carpenter's time locating and drilling holes and placing bolts at 87 c. per hour.....	13
Bolts, 1 x 9 in.....	5
Extra out to hold bolt upright angles to the forms.....	1
	19
With Special Inserts	
1 in. pressed steel insert.....	11
1 1/2 in. bolt to fasten face angles.....	2 1/2
Placing insert.....	2 1/2
	16
Saving in form of inserts.....	3

Bolts may be bent when struck by large scaffolding timbers, thus necessitating rethreading and they are often 1/2 in. or more out of line due to the sag in the concrete forms. With the insert an inch of adjustment is obtained and angle irons can be attached without the necessity of punching a new hole, even though the beam sags slightly. A bit of mortar is put in the bottom of the insert to provide a bearing surface. Mr. Johnson found that an insert should be placed on each side of the column to carry the angle across the face of the column, and used at every floor level.

Improvements in Creeper Loader

Three improvements are embodied in the new model of creeper loader, manufactured by the George Hais Manufacturing Co., Inc., New York. The width of the feeding element has been

increased from 7 to 8 ft., which more than doubles the clearance at the side of the creeper element. The machine also has been equipped with an improved type of heavier clutch. The third innovation is the use of a new design of tread link which renders the overlap self-cleaning and does away with any possibility of injury to bituminous pavements.

Among the former design features retained in the new model are the steel-plate feeding propellers, 2-ft. crowding speed, toothed buckets and completely inclosed transmission and clutches. The machine weighs 14,000 lb. and is equipped with a 37-hp. Waukesha gasoline engine.

Reducing Idle Time in Haulage

The problem of keeping motor equipment in continuous operation is intensive when the load must be handled piece by piece as in the case of lumber or iron pipe, or other products in small units. The accompanying illustration shows how, through

the use of a semi-trailer, the truck and its driver are kept constantly on the move in transporting dressed lumber.

The semi-trailer, made by the Trailmobile Co., Cincinnati, is parked on its own wheels with the front supported by a pair of jacks while the lumber is being loaded. When the trailer has its full cargo, the motor truck—which meanwhile has been busy hauling another trailer—backs under it. The fifth wheel or turn-table mechanism which is mounted on the truck and is provided with lift skids projecting to the rear automatically lifts the jacks free of the ground. The fifth wheel mechanism automatically connects the truck with the trailer. The jacks are swung up away from the ground to give ample road clearance and the entire outfit is immediately under way to make delivery.

Publications from the Construction Industry

Water-Tube Boilers—THE KIDWELL BOILER CO., Milwaukee, Wis., has issued a 208-p. volume on boiler design and operation, particularly in regard to the Kidwell two-flow ring-circuit water-tube boiler. This type of boiler, claimed to represent "a great advance over any previous design," is based on a principle of circulation discovered by Goldsworthy Gurney, the Cornish engineer, in 1826, but said to be not generally embodied in water-tube boilers. The design of such boilers, with numerous modifications, is described in full and illustrated by numerous drawings, as well as by photographs.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Bridge Construction This Year and Last

Statistics from *Engineering News-Record* covering bridge contracts of \$25,000 and over show two peaks in 1923, in May and in September. The May peak may be explained by looking at the chart of the Far West. During the month a 6-mi. drawbridge over San Francisco Bay costing \$10,000,000 was awarded. This of course is reflected on the chart of the United States.

The September peak was due to work in the Far West and the South. During this month the Far West awarded a contract of \$4,500,000 for the bridge over Carquinez Straits; a 2,480-ft. double-track steel railroad bridge over St. John's River, costing \$1,800,000, and a 1,733-ft. concrete bridge with two steel bascules over the Ashley River, costing \$1,067,466. Except for these two peaks both the 1923 and 1922 curves are fairly regular.

During the first eleven months of these two years, 1922 had 379 awards

with a total value of \$42,137,000 compared with 346 for 1923 valued at \$61,069,000. The average value of each award for 1922 was \$111,179 against \$176,500 for 1923. The trend of bridge construction may be gathered from the figures of the past five years:

Year	Total	Total for 11 Months	Monthly Average
1919	\$27,143,669	\$26,555,346	\$2,414,123
1920	35,213,881	33,199,984	3,018,180
1921	27,336,677	25,341,282	2,303,753
1922	43,477,000	42,137,000	3,830,636
1923	58,196,000	5,290,545

The total for the eleven months of 1923 exceeds the yearly total of any of the four preceding years and gives a monthly average of over \$5,000,000. The total for the last month of this year will place 1923 as one of the record years in bridge construction. A contract has just been awarded for a bridge over the Raritan River, at Perth Amboy, N. J., costing \$3,702,922.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for in Construction News, pp. 335 to 345, are the following:

Club, Philadelphia, Pa., Penn Athletic Club, \$2,500,000.

Office, Huntington, W. Va., Coal Exchange Bldg. Co., \$1,000,000.

Apartment Hotel, New York, N. Y., Warinick Corp., \$2,000,000.

Hospital, Ft. Worth, Tex., Ft. Worth Methodist Hospital, \$1,000,000.

Oil Removal Plant, Milwaukee, Wis., Dept. of Pub. Wks., \$1,500,000.

Industrial Plant, Toledo, O., Libbey-Owens Sheet Glass Co., \$1,000,000.

Railroad, Oregon, Southern Pacific Co., 7 mi. section to cost between \$2,000,000 and \$3,000,000

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 335 to 345, are the following:

High School, Hartford, Conn., to Southern New England Contg. Co., \$1,170,125.

Office, Philadelphia, Pa., to Stone & Webster, \$3,000,000.

Theatre, Bank and Office, Flint, Mich., to Wells Bros. Constr. Co., \$2,500,000.

High School, St. Louis, Mo., to H. C. Gerhard Bldg. Co., \$1,240,000, heating and ventilating to Sodeman Heating & Power Co., \$156,447; plumbing to H. D. M. Doerner, \$93,315; total \$1,489,762.

Improvement, Clearwater, Fla., to Davis Miller, Cone Bros., and Peninsula Constr. Co., \$2,413,858.

Bids desired on 40,000 cu.yd. of trench excavation on drainage system by Winterbottom-Connelly Co., 17,316 Madison Ave., Cleveland, Ohio.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Dec. 6; the next, on Jan. 3.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.....	\$3.64	\$4.00	\$4.40	\$3.30	\$3.55	\$4.20	\$3.60	\$4.10	\$4.25

Common labor, non-union, hour.....30	.30@.50	.82½	—40@.45	.35@.50	.50	.62½	.30

Explanation of Prices.—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered. except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93¢; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Shesboyan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. The price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5½ x 8 x 11½. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on white pine lumber, free on cars at mill. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.50). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

Buying is everywhere upon a conservative basis, owing to the tendency shown by most buyers to close the year with light reserve stocks of materials.

While there has been no decline in building trades wages, some concessions are forthcoming in materials prices. The lower prices in question are designed principally to induce a greater volume of winter building and also to give the dealers a chance to cover against the spring rush for building

materials and consequent mill and transportation congestion.

There is evidence, however, of a slight upward tendency in prices of materials used in the latter stages of the construction of a building.

The lumber market is taking on a firmer tone in most centers, although telegraphic advices from San Francisco announce a drop of \$3 per M. ft. in Douglas fir timbers.

Common brick are quoted at \$20 per

M. wholesale, alongside dock, New York, against \$19, one week ago. The winter reserve stocks are low, with danger of navigation in the Hudson River being closed at any time by freezing weather. This would of course cut off the supply of Hudson common brick in the midst of a period of active demand. The unusual supply of used brick from building demolition, as well as importations have not as yet affected the price of first grade domestic brick.

A Banner Construction Year in Prospect

WITH the end of the present year at hand, the thoughts of engineers and contractors turn to 1924. What is the prospect for construction during the next twelve months?

The answer, according to the forecast of *Engineering News-Record's* Construction News Department is:

\$5,000,000,000

This sum, if costs remain at their present level, will be spent on building and general construction in the United States during 1924, according to the best estimates now available. In other words, if no unforeseen events occur to upset calculations, a banner construction year is in sight.

Assuming that this huge sum will be expended on various classes of work in the same ratio as obtained during 1923, the figures are as follows:

The Construction Prospect for 1924

Streets and roads	\$1,250,000,000
Industrial building	350,000,000
Commercial building	1,250,000,000
Residential building	550,000,000
General construction	1,500,000,000
Total	\$5,000,000,000

VERTICAL CAPSTAN WINCH

Buffalo General Electric Company

ELECTRIC BUILDING
BUFFALO, N. Y.

RECEIVED

October 10th, 1920.

TRUCK EQUIPMENT CO.,
1636 Lafayette Ave.,
Buffalo, N. Y.

Gentlemen:

We have the most of our large trucks equipped with Mead-Morrison #501 heavy duty winches and they have been very satisfactory in handling our class of work, and we intend to make it one of our standard equipment.

Yours very truly,

BUFFALO GENERAL ELECTRIC CO.,

Chas. E. H. [Signature]
Capt. of Transportation.

E. A. S.

*“ . . . to Make It
Our Standard
Equipment ”*

A Vertical Capstan Winch saves time and labor. Equipped with it, your trucks can haul cable, raise poles, or do any of a great number of jobs—each at a minimum of expense. Write for full information.

Viewing the Nation's Wealth
Uncle Sam on an inspection tour of American properties stops to watch a big crane in one of his navy yards.

The Dutch Boy Painter:

"That floating crane can handle tons as easily as an elephant tosses straw. But neither its size, nor its power, can save it from ultimate destruction from rust—if its metal isn't protected!"

This 150-ton floating crane couldn't lift a rust-mortgage

UNPROTECTED metal surfaces soon become plastered with rust-mortgages. Every engineer knows what that means. The metal has been robbed of a certain part of its strength. What has been lost can't be recovered, but further loss can be stopped and future loss can be prevented—by red-lead.

Red-lead has for many years been recognized as metal's best protection against rust. It is the standard protection. Rust can't form where there is a well-maintained coat of red-lead.

Because it is pure red-lead, Dutch Boy red-lead supplies complete protection to metal surfaces against rust. Rust never holds a mortgage on metal that is guarded by Dutch Boy.

Dutch Boy red-lead sticks tight to clean metal. It forms a tough, elastic

coating which expands and contracts with the metal without cracking or checking. It becomes almost a part of the metal's surface. Dutch Boy red-lead costs no more than other good paints. In fact, its cost is materially decreased by its unusual spreading power.

You can get Dutch Boy red-lead as a paste and also in liquid form ready for the brush. The liquid comes as straight, untinted red-lead for shop painting and priming coats. It is also tinted to greens, browns and black for finishing coats. The untinted paste can be tinted to any dark color.

For the complete protection of metal surfaces, specify Dutch Boy red-lead by name—then stop. There is no "or equivalent."

Write for Painting Helps No. 5.

Accurate Decimal Points

SUPPOSE you had a Scratch Pad with Decimal Points printed on it. Then when you wrote the two factors of a decimal multiplication with the whole numbers to the left of the points and the decimals to the right, the correct answer would automatically appear, *accurately pointed off*.

Such a Scratch Pad would be valuable to you. Accuracy of decimals is equally as important as accuracy of figures.

The Monroe Calculating Machine gives you Proven Results, *accurately pointed off*, in just the same way. As you "write" the two factors of any problem in the machine, you immediately read the Proven Answer, with the decimal point in the correct place.

Ask to see why users say "the Monroe is the finest Scratch Pad ever given a clerk." The coupon below simplifies your request.

Monroe Automatic—Marks a new era in Mechanical Calculating and Adding. A portable, electrically-operated machine for use either on desk or stand.

To Add or Multiply, simply touch the Plus (+) Bar. To Subtract or Divide, simply touch the Minus (—) Bar. The Proven Answers automatically appear with split-second speed.

Monroe Standard Model—Every feature of the Standard Monroe is conducive to speed with absolute accuracy. A forward turn of the crank to add or multiply; a backward turn to subtract or divide.

Special Models to fit individual requirements—British Currency Model, Fraction Models, etc., on which all ordinary calculations may also be performed.

There are Offices rendering Monroe Service at all Principal Points in the U. S. and Canada and throughout the World.

whether you buy it or not"*

BOILER makers, car builders and structural steel fabricators alike express their preference for Little Giant Electric Drills when used on reaming and tapping operations.

This mark of distinction has been given to Little Giants because they are successfully meeting their requirements in hundreds of boiler and car shops, structural steel plants and other industries where the gruelling work encountered is a fit test for any tool.

The economy, service and dependability of Little Giant Electric Drills is attributed to their design and construction. Large overload capacity, low temperature rise, high efficiency and long life are a few of their many points of superiority that mean economical operation over a period of years.

You can use one or more of these Little Giant Electric Drills profitably on your reaming and tapping work. Bulletin 891 describes them in detail. Write for your copy.

These contractors held their good men all winter —at a profit

Of course it pays well to hold on to good men who know your ways. Steady employment, 12 months a year, attracts the best class of skilled labor and common labor.

You have often seen a *permanent organization* beat the lowest costs that can be gotten with transient labor, that is hired for only a single "season."

Every winter there are more contractors holding their best men together by working right through cold weather, and *making money doing it*. In some cases the profit-per-yard has run higher than the same contractors were able to make during the warm months of the same year, when keen competition bid the prices way down.

There have been very good results on winter cellar excavation, trench digging, stripping gravel pits, quarries, and shale pits, road grading that is fairly heavy, ditching, etc.

The ideal machine for cold weather is the ERIE Shovel—because of its greater digging power, and its steady reliability. Actual records kept by experienced owners show that their ERIE's cost only $\frac{1}{3}$ as much to keep up as other makes of shovels that they have used—with A CORRESPONDING SAVING IN WORKING TIME.

Write and tell us what kind of winter work you are figuring on. We will send records of similar work, in full detail—showing you just what can be done.

Laying Water Main: Any ERIE Shovel can be changed over in a few hours to a crane like the above, shown placing 30-in. sections of steel water main pipe, Akron, Ohio. Also handled 10-ton valves. Operating a clam-shell bucket, it did the back filling. One of 3 ERIES owned by P. F. Connelly Co., Cleveland.

Mid-winter road grading; two ERIES excavating 90% rock, with only light blasting.

"Two of our ERIE Shovels completed the most difficult piece of State Road work in Pennsylvania, 90% rock, and we had to shoot very light because of a parallel electric railway and canal. This left large tight stone, which the ERIES handled with very little repairs. We have owned other makes of shovels, but since we bought our first ERIE, we would have nothing else,"—R. C. Murphy, W. H. Murphy & Sons, Harrisburg, Pa. (5 ERIES)

Removing snow for street department at a good rental figure

C. C. Kilby, owner of the "A" ERIE above, saved the city of Hartford, Conn., 50% to 60% of the costs of removing 4 to 5 feet of ice and snow—and found profitable work for his shovels.

This 4 cu. yd. ERIE and 3 five-ton trucks did the work of 50 laborers and 10 teams, and did it quicker.

Mr. Kilby writes: "We are greatly pleased with the work of our three ERIES; have found them very fast, with plenty of power for heavy work."

HOIST BUCKETS

A
**20 year
leader**

For over two decades the Ransome Hoist Bucket has been prominent on the big concrete jobs throughout the world. It is used in conjunction with a straight back tower bin for a chuting installation or with a sloping back bin with cart distribution. The bucket operates quickly in a direct vertical lift. One of its great advantages is that no harm is done to the tower or bucket if the bucket is accidentally hoisted above the dumping point.

Its *simple and sturdy construction* makes each year's demand greater. Bulletin 202 gives complete information.

IRVING SUBWAY

TRADE MARK
(PATENTED) REG. U.S. PAT. OFF.
THE FIREPROOF VENTILATING FLOORING

Light, air, comfort, cleanliness, safety—all are assured in this runway back of the boiler battery, by its floor of Irving Subway.

In dark, cramped places or out in the open for narrow runways and walkways or for wide spaces—for indoor service or outdoor exposures—for every industrial purpose where safety, durability and economy count—Irving Subway offers advantages no other flooring affords.

It affords the utmost in strength with the minimum of weight—ease of installation and rearrangement—an absolutely and permanently safe, non-slipping surface—a smooth, comfortable footing to walk or work or wheel upon—the time-proofness, wear-proofness of steel—and (biggest factor of all, in value) the experience and responsibility of the oldest and largest manufacturers of open metallic flooring. Write for Catalog 4A5 and specify Irving Subway.

When One Pint of Water Wastes Two Pounds of Cement

Effect of Quantity of Mixing Water on the Compressive Strength of Concrete
NOTE: In general construction, the maximum strength can rarely be obtained, but it is possible to obtain 70 to 90 per cent of the maximum strength without additional expense by restricting the quantity of mixing water.

Observe this curve closely. It shows impressively the effect of the quantity of mixing water on the strength of concrete.

It is now known that excess mixing water, not only weakens concrete, but that it is actually wasteful of cement. One pint of water more than necessary in a one-bag batch decreases the strength and resistance to wear as much as though two or three pounds of cement were left out.

Here is a fact, which if brought home to the superintendent and the foreman, can be of great practical value in raising quality on the job.

Wouldn't you like to have, right at hand for quick reference, a practical manual which tells how the quantity of mixing water can be closely controlled, so as to give concrete greater strength without using any more cement?

Then write today for our free booklet, "Concrete Data for Engineers and Architects." We will be glad to send you extra copies for superintendents and foremen.

Take full advantage of the service the Portland Cement Association has to offer. One of the District Offices of the Association is always near you. Get acquainted with it.

Economies in Trench Excavation are effected by the Equipment you employ

Efficiency comes from Experience. And experience is not gained on the drafting board but on the job under actual working conditions.

Every Austin Trench Excavator has back of it forty years of "On-the-Job" experience.

Economies are effected through the use of larger power units, safety features that avoid breakdowns, heavy construction, patented devices and ability to dig anything that is classed as earth excavation.

This is AUSTIN TRENCH DIGGING efficiency summed up and the guarantee of economy on every job.

On Some Jobs

The "Wheel" Machine's The Thing

Cross-country road building needs the "Creepers Type" Path Digging Loader—but city work or material yard handling is just as well done with the "Wheel Type" Machine.

Has the wonderfully efficient Haiss Self-Feeding Propellers and a slow-speed drive

of 30 inches a minute to crowd it against the pile. Self-propelling, of course.

Digs and loads 1 cu. yard per minute (and better) in crushed rock or other material—and does all the work with a labor cost of one operator only.

"The man who owns one" buys a second out of the first one's savings. Repeat orders on Haiss Loaders are a matter of course.

A "Sure 'Nuff"

RIP-SNORTER

Users of the Austin Rip-Snorter know how appropriately it was named. When it comes to tearing up a hard-as-sin, worn out, rutted road surface, no other machine or method can touch it.

On maintenance work the Rip-Snorter scarifies and grades in a single operation, leaving the road ready for rolling. In the preparation of an old road for resurfacing, the blade carries the scarified material to the sides of the road to form the new shoulders, or can be easily loaded in wagons.

Special Rip-Snorter Bulletin H suggests many other uses that the practical road man will find for this most efficient machine. Write for a copy today.

The Brief Statement
Below Gives You the
Main Facts You Wish
To Know Regarding

SAUERMAN Power Drag SCRAPERS

In excavating bank deposits of gravel, stripping overburden, making cuts and fills, cleaning out reservoirs, storing and reclaiming crushed stone, gravel or coal, Sauerman Power Drag Scrapers are money-savers because they possess large capacity, yet require no great outlay to install, operate and maintain. They show greatest economy in handling materials distances of 200 to 400 feet.

Description—There are three distinct types of Sauerman power scrapers. "Excavator," "LeClair" and "Crescent," each best suited to a particular class of work. All are bottomless, hence self-loading and self-dumping. The operation consists simply of dragging the scraper back and forth over the deposit or pile that is to be excavated or rehandled. When the scraper reaches the dumping point, the operator causes it to deposit its load automatically by putting the pull-back cable in operation; one man at the levers of a double drum hoist controlling the complete operation.

Sizes—Standard sizes of Sauerman Power Scrapers are from $1/3$ to 5 cu yd. Larger sizes can be built to order as specified.

A portable power scraper outfit, designed for light excavating and material-handling, is offered in two sizes, $1/4$ and $1/2$ cu yd., with operating spans of 200 ft.

Service—If the illustrations here do not give you sufficient evidence of the adaptability of Sauerman equipment for your conditions and requirements, submit your problem to Sauerman engineers. Their experience, gained through contact with over 1,000 installations of Sauerman cableways and power scrapers, is freely at your service.

Tell us what you want to accomplish, daily yardage you require and the surrounding conditions and we will suggest the type of equipment and general layout that will give you the desired result at lowest cost.

MOUNTED on a motor truck a Universal can move from job to job quickly going anywhere your trucks will. On the job, quicker swing, and easy handling, piles up a big daily yardage. Witness this job, where a Universal is digging a trench 40 inches wide by 10 feet deep through hard top soil and stiff clay, removing 250 yards of material a day. This user has four Universals busy now, adding one at a time during the last three years.

Users are repeating on motor truck mounted Universals because of their absolute reliability, stability without outriggers, large daily output of highly profitable work, and their quick mobility. They can be mounted in many ways to suit your work. Write for Bulletin No. 22-N.

Batcherplant, as nucleus for central mixing and distributing system—Metropolitan-Edison Co., Middletown, Pa. power plant.

Carney was specified for the McKinley Junior High School at Cedar Rapids, Iowa, as it is for hundreds of buildings throughout the country because it builds a better wall.

Architects: Rush & Zalesky, Cedar Rapids, Iowa.

Contractors: Theo. Stark & Co., Cedar Rapids, Iowa.

Carney Sales Increase Each Month

THE merits of Carney have brought it into general use. Hundreds of Contractors know from practical experience that it saves time, money, and worry. Carney sales are increasing by leaps and bounds, due entirely to its good and saving qualities. Carney always builds a better wall at final lower cost. That is why we are building new mills.

Carney Has These Exclusive Merits

It can be used immediately after mixing or left in the box over night. There is no waste to Carney. Five bags to a barrel. Four and seventy-five hundredths cubic feet to a barrel. Four parts sand carrying capacity. It requires no lime, which saves time and labor in mixing. It prevents loss and waste through carelessness. Being more plastic and smoother working, the mason can work faster and easier

on the wall. It lays the maximum number of brick to the barrel. It is ideal for wall bearing buildings. It becomes harder than the brick and tile it binds, continuing to harden indefinitely as time goes on. It sets a creamy white, contrasting beautifully with brick and tile. The final cost of a Carney wall is always lower. Contractors bid lower, do better work, and make more profit with Carney.

This book tells the complete story of Carney. It will be sent free to anyone interested in building.

Insley Equipment for Handling Concrete

Marshall & Fox used INSLEY STEEL TOWER EQUIPMENT on the Drake Hotel job in Chicago, and now, on the addition to the Edgewater Beach Hotel are using the plant shown above. It consists of a 160 ft. Quick Shift Steel Tower, continuous line Insley Chutes, and an Insley Counterweight Chute which distributes the concrete.

Marshall & Fox are one of the many high class builders throughout the country for whom Insley Concrete Handling Equipment means complete satisfaction, as is best evidenced by the fact that they have used it not once, but several times.

Chemical Laboratory Building Ohio State University, Columbus, Ohio. Architect, Prof. J. N. Bradford. Contractors, D. W. McGrath & Sons. 35,000 sq. ft. Berloy $\frac{3}{4}$ -in. Ribplex used in the 2-in. solid walls and partitions.

Two-Inch Walls and Partitions

To the adaptability of reinforced concrete there is no end. Proper distribution of steel is one of the biggest factors in its success and for many forms of concrete work. Berloy $\frac{3}{4}$ -inch Ribplex has proven to be a very effective type of reinforcement.

Walls and partitions two inches thick with the ribs of the $\frac{3}{4}$ -inch Ribplex placed vertically were used to excellent advantage in the building shown above.

The same type of construction has been used in many other buildings in walls, partitions, floors, roofs, and in a wide variety of special concrete work such as bath houses, ornamental fences, drying ovens, hand-ball courts and, in fact, wherever a light, strong concrete slab is desirable.

Another very effective basis for two inch solid walls and partitions is the use of $\frac{3}{4}$ -inch Ribplex with ribs horizontal wired to Berloy cold rolled channel supports.

May we tell you more about this type of construction and its use? Please address Dept. F-24.

The Berger Manufacturing Co.

Canton, O., Boston, New York, Philadelphia, Chicago, St. Louis, Kansas City, Minneapolis, San Francisco, Los Angeles, Dallas, Roanoke, Jacksonville.

$\frac{3}{4}$ -Inch Ribplex

This is a stiff, expanded metal mesh with $\frac{3}{4}$ -inch ribs spaced 12 inches on centers. Covering width of ribs 1 to 21 inches, the ribs nesting together at sides and ends to make a firm, even splice.

$\frac{3}{4}$ -inch Ribplex has been used extensively as centering and reinforcement for concrete floors and roofs, walls and partitions and many forms of special work. Other Berloy Products include Lath, Ribplex, Diamond Mesh Lath, Metal Lumber and Floor Cores.

BERLOY

DIAMOND MESH LATH AND RIBPLEX

Inside view of wall or ceiling showing how fingers or "keys" hold plaster to wood lath.

Why does PLASTER crack?

Plaster and stucco crack, and sometimes fall off, because expansion and contraction of lath causes the fingers or "keys" which hold it in place, to break off.

National Stucco-Plaster Reinforcement eliminates "keys".

This combination of base and reinforcement becomes an integral part of and thoroughly embedded in, plaster and stucco, and thereby prevents cracking and falling.

It provides very much stronger stucco and plaster than any other type of lath or base. It automatically "back-plasters" itself. It is fire-safe and sound-deadening. It eliminates dust streaks, lath marks, and rust marks.

It is applied either direct to studs and joists, or over sheathing or insulation. It cannot be "skinned", yet takes less material because it eliminates "keys".

In all your work, use National Stucco-Plaster Reinforcement in place of lath, because it saves time, labor, and material, yet assures stronger plaster and stucco.

Our new catalog explains and proves *how* and *why* it is best to build with reinforced concrete, plaster, and stucco. Write for a copy—it is free.

Power and Economy

P&H Shovel—Electrically Driven

G. D. Francey of Wauwatosa, Wisconsin, works all of his equipment to capacity. His P&H one-yard shovel works steadily loading blasted stone—which every quarryman knows is hard service.

Being electrically operated, the machine starts at the throw of a switch. There are no fires to attend—no fuel or water hauling difficulties. With its powerful, positive and rugged chain-crowding motion, this machine scoops up a heaping load of stone at every pass. It's the ideal machine for quarry service.

One-Man Operated

Only one man is needed. There is no fireman or watchman. This saving in wages alone is a big item to every quarry operator.

A Money-Maker

The one big thing demanded of a shovel—is that it must be a money-maker. That the P&H is a money-maker is proved by the testimony of hundreds of users. Send for our book, "What Users Say."

Compressor Efficiency At Full and Partial Loads With the 5-Step Clearance Control

The demand for air is seldom steady even during any one day. Throughout the year it is bound to vary in accordance with the shop's production.

Your compressor must be large enough to meet the shop's present or contemplated maximum demand. At the same time it should operate efficiently when delivering partial capacity so that the cost of air does not become excessive when the demand falls off.

Class PRE direct-connected, electric motor driven compressors are extensively used where large volumes of air are required. The volume of compressed air delivered by

the compressor is efficiently regulated by means of the patented 5-step Clearance Control. With this regulation the compressor delivers automatically, full, three-quarter, one-half, one-quarter or none of its rated capacity. The horsepower required is reduced practically in proportion to the reduction in capacity.

Another feature of the 5-step Clearance Control is the maximum Demand Stop which prevents operation of the compressor at any higher maximum load than is desired. This is extremely important when a maximum demand of service charge is included in your contract for electric current.

Ingersoll-Rand

THE HIGHEST DEVELOPMENT IN CAST IRON PIPE

ARECIBO, P. R. wanted pipe for its water supply—reliable, durable, permanently tight pipe. “Universal” was laid because it possessed all of these essentials, *and more*—no expensive cumbersome joint-making equipment was needed, no time was wasted pouring and calking. The above line hugging the bridge is “Universal” 12-inch.

UNIVERSAL
the
CAST IRON PIPE
that Makes
its Own Joints

Ratchet Wrenches
the only tools—No
bell holes to dig.

The flexibility and tightness of its machined joints make “Universal” a great favorite for water supply, fire protection systems, sewage disposal, gas lines, subaqueous lines, and for other service where freedom from leakage is essential.

THE CENTRAL FOUNDRY COMPANY

Subsidiary of

IRON PRODUCTS CORPORATION

New York, Chicago, Birmingham, Dallas, San Francisco, Los Angeles

UNIVERSAL CAST IRON PIPE

tight, flexible, dependable—no lead, no calking, no bell holes to dig

As to Flexibility—

FLEXIBILITY in a pipe line is essential but hard to get. It should be provided for in the joints, in every joint.

We have perfected joints which allow for an extreme of flexibility with the result that many curves can be made with our standard pipe, without resorting to the use of 'specials'. Our expansion joints will expand or contract; open up on one side without opening on the other; open on the top or the bottom, and under all these conditions still remain tight, which means that Lock Joint Pressure Pipe is so constructed that its joints will take care of expansion, contraction and settlement, in addition to which they cannot blow out.

LOCK JOINT PIPE COMPANY

Pressure, Sewer, Culvert and Subaqueous Pipe
9 Rutledge St., AMPERE, N. J.
"Every Joint an Expansion Joint"

LOCK JOINT

Reinforced
Concrete Pipe

Meeting Special Requirements is one of the features of "NAVCO" service

Where clearance or other structural conditions make the use of standard valves, fittings, or piping accessories impossible, we can meet the requirements by supplying special valves, fittings, and other castings from our own foundry.

The above illustration shows a 30-inch gate valve in the condenser connection of a turbine, with a 14-inch side outlet for the atmospheric exhaust connection. The center line of the branch is offset $3\frac{1}{2}$ inches to clear the I-beams in the turbine foundation.

This, and many other small details, make up an entire piping job. Our experience in this field should be invaluable to piping men and consulting engineers.

*Send for our Catalog 5A. It should
be in the hands of everyone who
has to do with power piping.*

Cut Your Water Bill, Reduce Your Pumping Costs

The water that overflows from your tanks, standpipes, reservoirs, etc., represents a double loss—a loss in power required to pump it there, and a loss in water. Such waste can be eliminated *completely* by the installation of

GOLDEN-ANDERSON Automatic "Cushioned" Controlling Altitude Valves

They maintain a constant level automatically, without the use of floats or fixtures inside the tank. No human element is involved. These valves may be closed in three ways, (1) automatically by water, (2) by electricity (3) by hand. They may also be arranged to close automatically when a break occurs in the mains. When necessary, they may also be connected to "close both ways" in a single line of pipe.

No Metal to Metal Seats.
No Water Hammer.

Golden-Anderson Valve Specialty Co.,
1202 Fulton Bldg., Pittsburgh, Pa.

GOLDEN-ANDERSON Pat. Automatic Double Cushioned Triple Acting Non-Return Valves

1. Prevent shut-downs due to reversal of steam flow.
2. Instantly close and isolate a boiler when a tube bursts.
3. Cut off steam flow from every boiler instantly when a steam pipe ruptures.
4. Automatically cut a boiler into line.
5. Prevent backflow into cold boiler.
6. The only valves that can be tested in service.

Angle Globe or Elbow Pattern

No Bursting Mains

GOLDEN-ANDERSON Pat. Cushioned Water Relief Valves

1. Automatically relieve excess pressure.
2. Prevent stress, strain and bursting of mains.
3. Correct mechanical construction.
4. Perfect air and water cushioning.
5. No metal-to-metal seats. No hammering or shocks.
6. Angle and globe pattern. Sizes, 3 to 30 in.

Stop-starter attachment for centrifugal pumps

Every Valve with an Absolute Guarantee

GOLDEN-ANDERSON Pat. Automatic Cushioned Water Float Valves

1. Automatically Maintain Uniform Water Levels in Tanks, Standpipes, etc.
2. Instantly Adjusted to Operate QUICKLY or SLOWLY.
3. Floats Swivel to any Angle—Most Satisfactory Float Valves Known.
4. No Metal to Metal Seats—No Water Hammer or Shock.
5. Cushioned by Water and Air.

Hosts of References

GOLDEN-ANDERSON Pat. Automatic Double Cushioned Check Valves

1. Especially adapted for Water Service.
2. For High or Low Pressure.
3. Thoroughly Cushioned, No chattering, Hammering, or Sticking.
4. Globe or Angle Patterns up to 30 in.
5. Especially adapted for hydraulic elevator service.

GOLDEN-ANDERSON Pat. Automatic Cushioned Water Pressure Regulating Valves

1. Maintain a constant reduced pressure regardless of fluctuations on high pressure side.
2. Perfectly Cushioned by water and air. No metal-to-metal seats.
3. The best valve made for maintaining a constant low pressure where consumption is continuous.
4. Operates quickly or slowly as required—No attention necessary.
5. Positive to hammering or sticking. Sizes to 24 in.

No Water Hammer

GOLDEN-ANDERSON Pat. Cushioned Electric Water Service Valves

1. Give instant control of water distribution from pumping station in case of fire.
2. Open or close by electricity from distant points—A.C. or D.C. circuits. Also close by hand.
3. No waste of electricity. Current is on only few seconds.
4. Cushioned in opening and closing.
5. No water hammer, shock, sticking, surging or chattering.

No Metal-to-Metal Seats

POWER

Stone & Webster power stations designed and built, or now being built, total one and three-quarter million horse power—enough to operate the traction systems of New York, Chicago, Philadelphia, Detroit, Cleveland and St. Louis—our six largest cities.

Under construction is over 300,000 horse power. This is to supply Boston, Washington, Hartford, Lynn, Indianapolis, Fall River, Los Angeles and other cities.

Sixty public service corporations are served continuously by Stone & Webster engineers who make their plans and install their new generating and distributing equipment.

Stone & Webster engineers have examined and appraised properties to the total value of more than \$4,500,000,000 including many of the country's foremost public utilities.

Everything in Steel When You Need It

WHETHER it's reinforcing bars and spirals or beams, bars, rails, bolts, rivets, or any other steel product needed by the contractor—Ryerson is the logical source.

First, because you can rely upon immediate shipment from our large and complete stocks. Second, because of our facilities for bending or cutting to the exact size you require. And third, because Ryerson *Steel-Service* may be taken literally. Our engineers—and in fact every member of our organization is ready to go out of his way to help you get the steel *where* you want it and *when* you want it.

The Ryerson Journal and Stock List contains complete information on all steel products—have you written for your copy?

Jeffrey Material-Handling Equipment as used by the Fisher Body Corp'n

Where Jeffrey Equipment
is used—

Wood Apron and Rubber Belt Conveyors

Where Jeffrey Equipment
is made—

AT the Pontiac plant of the Fisher Body Corporation, the Jeffrey Belt Conveyor shown in the left hand illustration saves labor by handling waste wood or wood scraps from woodworking machines to storage.

This conveyor is 320 feet long, measuring 155 feet between centers; and travels at the rate of 100 feet per minute. It uses 24-inch four-ply canvas belting,—with 24-inch five-pulley troughing carriers mounted on wood base boards, and 24-inch standard flat belt carriers serving as return idlers.

The Jeffrey Conveyor shown at the right is

part of a Jeffrey Wood Apron Conveyor System comprised of three units, employed to handle boards or finished wood shapes at the Pontiac plant.

One unit, 400 feet between centers, uses 1615 feet of Jeffrey No. 126 Malleable Roller Chain. Another unit 130 feet at centers, utilizes 530 feet of the Chain; and the third unit, which is 245 feet between centers, uses 990 feet of the Chain.

Dependable, continuous operation is expected of these Jeffrey Conveyor systems — and is given.

MATERIAL HANDLING EQUIPMENT

Proud of It!

And with good reason. A few years ago monster cast-iron pots like these were regarded as "unweldable". In out-of-the-way places they were allowed to accumulate and encumber the smelter yards, because of the expense of breaking them up and transporting them to a scrap market.

The reclamation of "lead pots" is now a standard practice—thanks to the oxy-acetylene process. The big fellow shown here is one of twenty-six 8-ton cast iron pots reclaimed by a large mining and concentrating company in the west.

Thus one more intricate and difficult puzzle has been solved by oxwelding. It is typical of what Oxweld Resident Engineers (located in over fifty cities) are daily doing for the metal industry. They are ready to work on YOUR cutting and welding problems—to point out economical short cuts, reclaim scrapped pieces, speed production. Send for illustrated book "Oxweld Can Do It".

No. 2 Brownhoist crawler truck crane equipped with 40 foot boom and Brownhoist one yard clamshell bucket

This Small Crane Will Cut Road Building Costs

Road Show

A moving picture showing approved methods of building roads in several states and also a No. 2 Brownhoist 8-wheel crane will be shown at the Road Show.

Small in size and low in cost, this No. 2 Brownhoist Locomotive Crane has a remarkable handling capacity. It handles a one yard Brownhoist clamshell bucket easily and rapidly. The forty foot boom provides a wide handling radius and increased clearance for loading into bins.

In road building, large savings can be effected by the use of this crane in the handling of sand, stone, gravel, etc. The No. 2 Brownhoist is made with crawler trucks and four or eight wheel railroad trucks—powered either by gasoline or steam engine.

These different types are built so as to provide the most economical crane for the individual requirements of each user. We'll be glad to help you choose the one best fitted for your job.

Number 26

Winter Building Facts

WINTER building possibilities assume an increasingly favorable aspect as records of fact are substituted for current opinion. Discussing, recently, steel-skeleton building construction before the New York Building Congress, J. Reid Kilpatrick, Vice-President, Geo. A. Fuller Co., announced that careful statistics covering the firm's operations from 1912 to 1922, a period of ten years, show that the average number of days a year when a winter building program "would be rendered impossible due to temperature conditions" is fourteen. Any increased hazard, because of ice and snow, of winter steel-building construction was not indicated by the firm's records. Nor was it indicated that there was any difference in cost between work begun in winter and that begun in summer. Advocates of a twelve-months-a-year construction industry have always been hampered by lack of quantitative data on winter building conditions. These figures and those published three weeks ago, being developed by the New York Building Congress, serve in a small way to supply the deficiency of facts. It would be a fine thing for the industry if other contractors' organizations would emulate the practice of the New York builders in amassing facts to strengthen the waste prevention arguments becoming somewhat dulled by repetition.

Railroads Using the Highways

AN INNOVATION in freight service put into effect on the Pennsylvania R.R. appears to be a reasonable start toward co-operation between rail and motor transport. On one of its busy lines the local business in less-than-carload lots of freight has been so reduced that the operation of way-freight in this special service is no longer profitable. Consequently the railroad company has abandoned the service and has made arrangements with a trucking organization to call at its stations for the small amount of package freight that is still offered to it for transportation. As a means of doing away with an unprofitable service, this arrangement is admirable. Advocates of store-door delivery may claim that the handlings of the packages should be reduced from four to two by having the trucking concern call for and deliver the packages rather than have the packages delivered to the railroad freight sheds before they are turned over to the truck for movement. Such an arrangement, however, would require the heavy truck used for the long distance moving to do a great deal of traveling in collecting and distributing the individual packages which can be, and now is done by light cars or carts which most concerns maintain for their local business. In addition, the new arrangement probably simplifies the bookkeeping in connection with payment for the shipping, as most concerns of any size have current freight accounts with the railroad company to which the cost of the smaller shipments can

be added without the cost of individual collection or of a separate account, which would be necessary under the method of having the trucking company handle the shipment from origin to destination.

To Emphasize Progress in Concrete

IN 1904 the National Association of Cement Users was formed, in recognition of the need for some scientific study of the then infant concrete industry. Next year, in February and at Chicago, the society under its present name, the American Concrete Institute, will celebrate the twentieth anniversary of its founding. Twenty years is not a long time in history of most of the arts, but it comprises practically all of the maturity of the art of designing and making concrete. Because these twenty years have seen concrete rise from the position of foundation material to an almost universal medium of construction expression, the Institute is going to take advantage of the double decennial anniversary to emphasize the progress that has been made. One day of the meeting at Chicago, Feb. 27, is to be devoted to the story of concrete development. The committee which has the meeting in charge has outlined an excellent program with speakers who know the subject and with an exhibit in an adjoining room, both of which should be of exceptional interest. The regular meeting of the Institute will have its usual appeal to those who are concerned with concrete. The inspirational appeal of the one-day session of historic value in concrete should make the February meeting unusually attractive.

Too Big an Undertaking

THE Interstate Commerce Commission, in reversing its decision of last June in which it denied the Virginian Ry. the right to build a short branch line into a new coal field, has taken a step which would imply that it has seen the un wisdom of attempting to control production by determining which coal mines could or could not be opened. The unusual feature of that earlier decision was not that by declining to let the railway build tracks into the new mine the commission did indirectly prevent the opening of the mine, but that the commission specifically stated that in its opinion the mine should not be opened; giving as a further reason for its decision against the building of the spur the fact that the railway had been unable to supply sufficient cars for the mines already in existence along its lines. The far-reaching importance of such a decision is evident, for—lacking the powers of concentrating on coal suggested for it by the report of the Coal Commission—the Interstate Commerce Commission could not well undertake to regulate production in the coal industry unless it also were prepared to regulate production in other industries. It is well that it was able to seize upon the large increase which the

Virginian Ry. has made in its coal-handling facilities as a means of withdrawing from an awkward position in which it had placed itself by an ill considered attempt to improve the coal situation.

Flimsy Prophecies

PROPHECY was ever a precarious occupation, successful only so long as the prophet could preserve a Delphic impartiality or until some one took thought to check up the outcome of past prophecies. The numerous professional economists who have been earning a living for some time forecasting the trend of business have run up against the latter barrier. Someone in the Department of Commerce became curious enough a few weeks ago to compare the course of business with what a dozen or more forecasters said it was going to do. The results are not without humor. In an average of the prophecies of fourteen agencies, 40 per cent proved true and 60 per cent never occurred. The best record was made by a national bank which scored 85 per cent hits. The worst was the most celebrated—or notorious—of the prophets, whose forecasts are accompanied by charts of such astounding complication and color that we have always doubted whether the maker himself knew what they meant. He was right 15 per cent of the time! One ought to do better than that with a ouija board. Some day there may be enough statistical information available to enable one to out-guess the future. But even then it will be merely outguessing and there will be so many ulterior and unpredictable influences at work that it will be subject to the failure always inherent in a guess. To claim that any prediction made on the limited information now available is more than an expression of judgment comes pretty close to soliciting money on false pretenses.

Restricting Business Information

GENERAL business forecasting is so doubtful because the subject is complicated and because, too, all calculations may be thrown out of joint by unexpected national and international actions. To take the most obvious example, no prophet in the spring of 1914 knew that an assassination soon to take place in an obscure Serbian town would throw into the discard all the carefully built up data of past economic performance on which might have been predicated the forecasts of the business situation in the coming summer. On the other hand forecasting of a single business is simpler, and while subject also to the major ebbs and flows of economic conditions is most dependent on existing conditions in the trade or business itself. For that reason statistics of his trade or business—authentic and prompt—are the most valuable aids a business man can have in judging how much to produce. Such figures do not forecast for him the demand for his goods; that is something he must learn from other sources, but they do give him a line on the total supply and make less possible the slumps and booms due to ignorance of supply conditions. It is unfortunate, therefore, that the consent decree formulated by the Department of Justice in the tile manufacturers' case apparently prohibits a trade from collecting such statistics and throws the whole onus of such collection on the government. Up to date the government has not been prepared to provide the machinery or the funds, both necessarily large, to carry on such work. The interpretation of the Sherman Act as to trade statistics is running to absurd lengths.

Federal Aid for Roads

ENGINEERS and contractors need to keep in mind that the Congress now in session has before it the task of continuing or, as may be considered, of changing, the federal-aid road law and also of providing appropriations, if federal aid is to be available beyond the present fiscal year. Acting officially in convention the Association of State Highway Officials has asked for an allotment to the states of \$100,000,000 a year of federal aid for a period of three years from June 30, 1925. This amount is not too great for the states to absorb if they get about the task of building roads. Just now their delay, or, more accurately, the delay of some, in matching the federal-aid funds and placing work under contract is furnishing the best excuse that Congress will have that appropriations may be reduced and that the present law needs changing. There will be other influences to swing federal activity in road building to a separate system of national highways, to sectional highway systems or to some other object than is contemplated in the present federal aid law. Direction of Congress has to come from engineers and contractors. They are organized to furnish it. The general public, though wanting roads and aid in roadbuilding, may not be expected to take direct action. Contractors' associations and engineers' societies have the important duty this winter of seeing that our present efficient plan of organization for federal-aid road construction is not changed without real reason and that the present liberal appropriations for roadbuilding are continued.

Chances in Garbage Disposal

TWO narrow escapes from the fate so common to garbage disposal plants present themselves for record. The cities are Wheeling, W. Va., and Sacramento, Calif. At Wheeling, a Balmer incinerator, the first of the kind in this country, was put under contract early in 1923. About the time the plant was completed a local election substituted one faction of the dominant political part for another. Straightway began the attempt common under such changes to discredit what had been done by the previous administration. The new Balmer incinerator was beclouded for some weeks but although a test made under the new administration resulted in a report indicating that the plant was far below contract capacity the incinerator was finally accepted. Possibly the local authorities learned of the failure of new city administrations of San Francisco and Atlanta, some years ago, to throw new incinerators onto the hands of the contractors. Both cities were beaten. Atlanta recognized it and has used the furnaces since. San Francisco has tried to make victory of defeat by letting the new incinerator stand idle for many years, while continuing to use destructors of another British type, built in the nineties.

The experience at Sacramento was different in detail, although there also an incinerator came no one knows just how near to abandonment, soon after if not before completion. Just as the plant was nearly ready comes a "senator" of mystery with a proposal to enter into a contract for garbage collection and disposal. The city was priding itself on its collection system it had recently established, and on its new incinerator progressing towards completion and use. Apparently the "senator" had considerable support for his scheme, so concerned were some of the city officials lest it be adopted. Opposi-

tion and questioning led to a modified proposal. The plan was not without attractions, since on its face, an operating charge was to give place to revenue for the city. What seemed to be a joker appeared in the revised offer, in that the city was to stand ready to take whatever refuse the "senator" and his friends saw fit to turn over for disposal in the incinerator, evidently at the city's expense. While this would have put the furnace in use as a "standby" it would have been immediate partial abandonment, at the least.

Such are some of the garbage disposal chances being taken in considerable numbers all over the country by cities and contractors alike. They will continue until both see that it is for their interest to have garbage disposal put on a sound engineering basis.

Earthquake Construction

MUCH information is afforded by the views of Japanese earthquake damage printed in this issue. These views, supplied by a number of Japanese readers of *Engineering News-Record*, show the effects produced on civil engineering structures of different kinds, effects which range from the cracking of buildings to the shaking apart of earth masses and bridges. Broadly, the showing agrees with that of other earthquakes; but it is much more important, because of the greater variety of the effects as well as the greater violence of the earthquake. The effect on the railways, especially the culverts, fills, trestles and bridges, as shown in the views—only a few of which can be given for lack of space—is much more severe than most American engineers have realized.

In considering how all such effects may be guarded against by the designer and builder, it is well to bear in mind that earthquake action is dynamic, while the usual structural problem and the methods of analysis applied to it are exclusively static. The difference sets up a formidable difficulty, particularly because the structural engineer will hardly be willing to subordinate his static analysis, which deals with the important service needs, to a radically different kind of calculation, applicable perhaps only once in the lifetime of his structure. The ready way out of the difficulty is to convert the data of the dynamic action into static terms. This course has been followed by the Japanese students of the subject, and is reflected in the brief summary of design principles presented in this issue.

So long as the equivalent static analysis remains well within the range of experience and embodies a fair safety allowance, it should lead to satisfactory results. Accordingly we may consider the general case of buildings to be within reaching distance of solution. Extensive data are furnished by observations on city buildings of structural engineering type. Extending these data to dwelling houses and special types of building may require much careful study, but should be thoroughly feasible. Thus, we may hope to render building construction reasonably secure against earthquake ruin—at least in theory; in practice it may not be found economically desirable to incur the cost of providing this security.

Other structures are not in the same favorable condition, however. Chimneys, high bridges and earthwork constructions come in this category, and these all present special problems that do not appear to be amenable

to an equivalent static analysis. The case of the chimney is the simplest of these, and it does not seem impracticable to apply dynamic analysis to this particular problem.

The problems encountered in bridges and earthworks, however, are decidedly more refractory. Such structures are affected in puzzling ways by violent earthquake motions, as some of the illustrations show. It appears that a great deal of further study of shaking forces and resistances will be required before this part of the earthquake problem can be considered on the way to solution.

Financing Subway Construction

FOLLOWING closely upon the report of the Detroit Transit Commission recommending that the cost of new rapid-transit facilities be paid for by assessing the major portion of the cost on the local property which the subway benefits comes an independent recommendation from property owners along Sixth Avenue in New York City that the Sixth Avenue elevated railway be replaced by a subway financed by the property owners along the line. The Sixth Avenue property owners believe that the increase in the value of their property due to the removal of the elevated structure would more than repay them for the increased assessment.

The theory of assessing the cost of subways on the benefited property is not a new one. It is written into the present Rapid Transit Act in New York, but this is the first time that it has been proposed as a means of financing a specific piece of new construction. Its advantage is just as clear in New York as in Detroit, for, as we said in commenting on the Detroit plan in the issue of Dec. 13, the city is so near its debt limit that it is not in a position to finance all the needed rapid transit, nor are the people anxious to have the interest on the city debt continually increasing. Under the bond-issue plan there is little possibility of the city undertaking the replacement of the elevated structure for years to come. What money it can spend will be spent on building additional subways. Financing by assessment makes possible an otherwise impossible piece of construction.

It has still another advantage. The cost of construction is a direct charge upon the property of shrewd business men who can be depended upon to see that the money which they raise is not spent in the lavish way in which city money is usually spent, nor will they allow a large part of it to be absorbed in paying excessive prices for property rights or supposed damages to abutting property.

In the case of the Sixth Avenue elevated replacement there are many difficulties in the way of carrying out the proposition, but fortunately it is backed by a group of business men who realize that the removal of the noisy and unsightly elevated structure will make Sixth Avenue second only to Fifth Avenue as a business street. The stimulus which this realization has given their efforts is assurance that the project will be undertaken in the near future. Their efforts will be watched with interest by the advocates of more rapid-transit facilities in all our large cities. There is no reason why the same method cannot be applied wherever lack of city funds or disinclination to spend them for such purposes prevent construction.

Earthquake Characteristics and Building Resistance

A Summary of Basic Laws and Constants Deduced From Measurements of Earthquake Motions, and Checked by Observation of Damage Done by Recent Severe Earthquakes

By R. E. J. SUMMERS

Assistant Chief Engineer, H. K. Ferguson Co., Cleveland

DURING the past year the writer made a study of questions bearing on earthquake resistance of buildings, in connection with the design of a new plant for the Shibaura Engineering Works of Tokyo, Japan, for which the H. K. Ferguson Co. was consulting engineer. No literature in English being available, reference was made entirely to works of Japanese investigators. The works of the Imperial Earthquake Investigation Committee during the past twenty-five years constitute a treatise on the subject. An abstract of what they indicate, when taken in conjunction with observations on actual earthquake effects, is given in the present article.

To explain the problem in hand, it should be said that the Shibaura Engineering Works, a Japanese-con-

trolled organization affiliated with the General Electric Co. and manufacturing similar equipment, decided to build a new plant modeled on best American practice. Plans were to be made in their offices by their own staff, the writer acting as consulting engineer and supervising and checking the plans and specifications. The plant will cost 50,000,000 yen, or \$25,000,000. The first of the three construction sections, drawings for which have been completed, includes a heavy machine shop, 304x850 ft.; a forge shop, 186x200 ft.; a pattern shop, 70x300 ft., two stories high; and a warehouse, 70x400 ft., three stories high; together with a central heating plant, sewage disposal plant, and minor items. The machine shop will be twice as large as any factory building in Japan, and will be of steel frame, with large high spans and heavy cranes. The two multistory buildings are of concrete flat-slab construction.

FIG. 1—SIMPLE HARMONIC MOTION IN EARTHQUAKE VIBRATIONS

trolled organization affiliated with the General Electric Co. and manufacturing similar equipment, decided to build a new plant modeled on best American practice. Plans were to be made in their offices by their own staff, the writer acting as consulting engineer and supervising and checking the plans and specifications. The plant will cost 50,000,000 yen, or \$25,000,000. The first of the three construction sections, drawings for which have been completed, includes a heavy machine shop, 304x850 ft.; a forge shop, 186x200 ft.; a pattern shop, 70x300 ft., two stories high; and a warehouse, 70x400 ft., three stories high; together with a central heating plant, sewage disposal plant, and minor items. The machine shop will be twice as large as any factory building in Japan, and will be of steel frame, with large high spans and heavy cranes. The two multistory buildings are of concrete flat-slab construction.

Earthquake Period and Amplitude—An earthquake is a sort of simple harmonic motion (Fig. 1) similar to the projection of a circular motion on a straight line. If t is the time of travel of one circular motion, r the radius of the circular motion, v the speed of the circular motion, and a the acceleration toward the center of this circular motion, then

$$v = \frac{2\pi r}{t} \text{ and } \max. a = \frac{v^2}{r} = r \left(\frac{2\pi}{t} \right)^2$$

Applying these terms to the earthquake movement, we have its acceleration, a , expressed in terms of its period t and its range of motion or double amplitude $2r$. Therefore, if from seismograph diagrams we read that with a period of 1 sec. the range of motion is 100 mm., then $a = 50 \left(\frac{2\pi}{1} \right)^2 = 2,000 \text{ mm./sec.}^2$

Should unsatisfactory seismograph records be secured, the horizontal acceleration of the earth motion can be calculated from observing overturned objects, such as pedestals, tombstones, etc., by using the formula $a = xg/y$, in which g is the acceleration due to gravity, y the height of the center of gravity, and x the horizontal distance between the c.g. and the edge about which the body is overturned.

The force exerted by an earthquake on any structure can be expressed in terms of the weight of the structure, W , by the basic formula $F = Wa/g$. The coefficient a/g is called the *seismic coefficient*, denoted by K ; the earthquake force F equals the dead weight multiplied by this coefficient. For example, if $a =$

2,000 mm./sec.², then $K = \frac{2,000}{9,800} = \frac{1}{5}$, so that the

total force due to the earthquake $= \frac{1}{5} W$, or $\frac{1}{5}$ of the dead weight of the structure.

Seismic Coefficients—Before the last quake, the Tokyo Weather Bureau had established the maximum seismic coefficient to be used in design at $\frac{1}{10}$, which is that caused by an earthquake with an acceleration of 1,000 mm./sec.² This is the recorded size of the great quake in Tokyo of June 20, 1894. The great quake at Nagoya on Oct. 28, 1891, however, had:

$$a = 2,600, \text{ or } K = \frac{1}{4}$$

With these varying seismic coefficients, the designing engineer should consider the probable life of the structure on which he is working, the cost of it, and the cost of increasing his coefficient. Earthquakes in Japan occur apparently in cycles, with a great one every 60 years, like the one of Sept. 1, 1923, which was almost on schedule. With this in view it would seem probable that the use of $K = \frac{1}{5}$ would give ample protection for buildings now being built.

In a one-story building the force $F = KW$ is applied horizontally at the top of the sidewall, and stresses caused thereby are figured the same as for wind stresses. In a multistory building the lateral force is considered transferred by each floor, and roof slab, and the stresses are calculated the same as for wind stresses.

It has been observed that an earthquake never occurs while the wind is blowing, but always in a dead calm. This was especially evident from reports of the latest quake, when the high wind prevalent in the morning quieted to a dead calm with oppressive heat just before the quake. Because of this it is not necessary to add the wind and earthquake stresses in securing the maximum stress.

Japanese Construction—From these considerations, it is evident that the lighter the building, especially in the upper parts, the less it will be affected by a quake. The typical Japanese building is exactly the reverse of this, and therefore is easily shaken down. They use a light, flimsy wooden structure, with a very heavy tile roof. The columns, joists and beams are mortised

FIGS. 2 TO 7—SIX VIEWS OF DAMAGE DONE IN

Fig. 2—Maruzen Book Store, principal damage in upper part.
 Fig. 3—Destruction of tile-roofed houses in Dozakaka (street).
 Fig. 4—Street cracked off Mitsuokoshi department store building.
 Fig. 5—Uninjured modern buildings, Ginza Building under construction.
 Fig. 7—Asakusa ward, effects of the after earthquake.

together so that a column is so cut to pieces that one expects to see it break in two when being lifted into place.

As the streets are very narrow, the safest place to stand during a quake is under a lintel. Here one is protected from tile sliding off the roof, or from the roof collapsing inside. In a multistory office building the safest place is the center of the room, as the partitions are most likely to be thrown down, and the center of the room is equidistant from all walls.

Where Cracking Occurs—Every structure has a natural period of oscillation dependent on its shape, size and homogeneity. If this period of oscillation is longer than the period of the destructive earthquake motion, it can be classified as a tall column; if its period is shorter than that of the quake, it is a short column. The period of the destructive earthquake is 1.0 to 1.5 seconds. For a tall column, such as a brick chimney, the tendency to fracture will be at $\frac{2}{3}$ of the height above the ground; in a short column, the tendency to fracture will be at the base. The multistory office buildings recently built in Tokyo come under the lat-

ter category. In the usual building of this type, the first story is so massive and so integral with the foundations that it can be assumed as part of the foundations, so that fracture would tend to be in the second story.

This was first proven in the earthquake of April 26, 1921, when the Marunouchi Building, then under construction, had almost every pilaster in the second story cracked at an angle of 45 deg. Observation of the effect of the latest quake on the Palace Hotel, a building of same height, shows the steel column at the second floor offset 3 to 5 in. to the west and 5 to 10 in. to the north, and all of the second-story walls thrown down.

Overturning and Vertical Force—The stability of a building against earthquakes is proportional to its size and not its weight. If b and h are the breadth and height of the building, W its weight, and F the horizontal force tending to overturn, then the overturning moment is $\frac{1}{2} Fh$ and the stability moment is $\frac{1}{2} Wb$. Hence, when $Fh - Wb$ is greater than zero the building will overturn, and when it is less than zero the building will not overturn. Or, since $F = KW$, danger

or safety are indicated by K being greater or less than b/h .

Earthquake motion, though sometimes very violent, is continuous and does not consist of isolated jerks or shocks. The idea prevalent among laymen and some engineers that in destructive earthquakes buildings are first uplifted by the vertical motion, and then destroyed by being suddenly thrown downward is quite in error.

In ordinary cases the vertical component of the earthquake motion is much smaller than the horizontal. For instance, the severe Tokyo quake of 1894 registered a maximum horizontal motion of 73 mm., while the maximum vertical motion was only 11 mm. Therefore the damage was essentially due to the horizontal motion. This has been remarked in every quake recorded, so that we can assume that the vertical component is of secondary importance, and, except in cases of the foundation sinking, the entire damage is done by the horizontal motion.

The stability of a building is also affected less by the vertical motion than by the horizontal. This is shown as follows, using the same building and notation as above: If a' is the acceleration of vertical motion, then $\frac{W}{g}(g - a')$ is the effective weight when movement is down, and $\frac{W}{g}(g + a')$ is the effective weight when movement is up. The overturning moment due

to horizontal motion = $\frac{Wah}{g \cdot 2}$ or $\frac{1}{2}KWh$, while the minimum stability, when vertical motion is down, is $\frac{W}{g}(g - a') \cdot \frac{b}{2}$. Therefore $\frac{Wah}{g \cdot 2}$ must exceed $\frac{W}{g}(g - a') \cdot \frac{b}{2}$ for danger from overturning, or danger is present when $\frac{a}{g - a'}$ exceeds $\frac{b}{h}$.

Orientation of Building—Due to the shape of the range of mountains on the main island of the Japanese Empire, the direction of earthquake motion at Tokyo is always east and west. In making the plant layout for the project in hand, it was possible to put the length of the buildings east and west, making the bracing a more simple problem. On the machine shop and forge shop the roof deck was made of 2-in. dressed and matched Oregon fir supported on steel purlins, in order to secure a light, rigid surface that cannot crack and fall, be shaken out of position or slide off. All monitors are provided with continuous top-hung standard rolled steel sash glazed with 1-in. wire glass, being light and giving light, and the wire glass making for safety in case it should be cracked. This combination of light roof with heavy columns required for the cranes approaches the ideal as to relation of component parts of a building for best resistance to earthquakes.

Due to the excessive wind on the coast line at the building site, the structures were designed for a 30-lb. wind load. The Japanese code, by the way, allows no increase in allowable stress for combined wind and dead-load stresses. Using the usual designing seismic coefficient $\frac{1}{4}$, the total horizontal force proved to be less than one-third of the total pressure of the wind. These stresses not being coincident, the structure actually is proportioned for a seismic coefficient three times that assumed, or $K = \frac{1}{4}$, which is the same as that registered for the severe earthquake of 1891.

It is interesting to note that this checks the statement of the committee on buildings of the American Society of Civil Engineers which reported on the effects of the San Francisco earthquake of April 18, 1906 (*Trans.*, Vol. LIX, p. 208): "Sufficient evidence is at hand to warrant the statement that a building designed with a proper system of bracing to withstand wind at a pressure of 30 lb. per square foot will resist safely the stresses caused by a shock of an intensity equal to that of the recent earthquake."

Actual Earthquake Destruction—Generally the non-synchronizing in horizontal motion of the walls and roof is doubtless the principal cause of the destruction of brick buildings. It has been noted that one-story brick buildings are most damaged at the junction of the walls and roof, and that the two-story ones similarly are damaged most at the junction of the upper walls and the roof while the lower walls remain uninjured or little affected. This is evidenced in Fig. 2, showing a three-story brick building located on the main street in Tokyo. Again, in Fig. 3 the top of the tower rests in upright position in the street, indicating that the heavy top failed to synchronize with the walls and, the range of motion being quite large, was projected bodily into the street.

In Fig. 4, note the usual Japanese style of building, with the heavy tile roof, flimsy walls, with windows of light frames covered with paper, and a typical failure from earthquake.

Fig. 5 is a view of the Ginza (the only paved street in Tokyo, and the main business street) taken from Owaricho, the main intersecting street. Note the burned street car in the foreground. The exposed steel frame on the right is the new Ginza Building, twelve stories high, just under construction, and apparently plumb and safe, with only the concrete hoist tower askew. Incidentally, this steel was erected and being riveted in December, 1922, when the writer arrived in Tokyo; with work apparently uninterrupted, riveting was still under way in August, 1923. The uninjured concrete and brick building on the near side of the Ginza Building is also new. The large building in the distance, apparently in the center of the street, is the office of the Yokohama Life Insurance Co., of heavy stone masonry construction, and is about opposite the building shown in Fig. 2. The small wrecked buildings shown were of poor flimsy construction, likely to fall down with small excuse.

Fig. 6 is a view of the Mitsukoshi Department Store, a very modern and popular store, the showplace of Tokyo. The structure is of reinforced concrete. Its exterior walls are heavily scored to hold the stucco. In pouring concrete, the Japanese use soft unplanned wood forms and take no care in rodding and tamping the wet concrete. When forms are stripped, the surface of the concrete is full of voids, very rough, uneven, and covered with small splinters. Over this is placed a 3-in. cement plaster coat, well troweled and painted with liquid hardener. As there are hundreds of small quakes every year, this plaster coat peels off every three or four years and has to be replaced. This picture also indicates the truth of the general observation that the main damage done in the recent disaster was by fire and not by earthquake.

Fig. 7 is a view of Asakusa ward in Tokyo, in which was located Asakusa park, Tokyo's Coney Island. Note the two concrete buildings and chimneys in the

background, with steel sash still in place. Also note that in all of these pictures the poles are still standing, being one piece of evidence that the quake was not so severe in comparison with previous ones. Thousands of buildings withstood the shock, only to be burned in the fire. This was especially true in Yokohama. The greater part of the homes on The Bluff (the foreign residential section) were much shaken by the quake, but still stood Saturday afternoon, only to burn later.

The writer is indebted for much of this information on earthquakes to the papers of the late Dr. F. Omori, Tokyo Imperial University, which were published in the Bulletin of the Imperial Earthquake Investigation Committee, and to his personal courtesy and help; also to Dr. T. Naitow, of Waseda University, Tokyo, for many of his articles and much advice and assistance in translation; and to P. K. Kishi, engineer for the H. K. Ferguson Co., for assistance in translation.

Earthquake Damage to Japanese Government Railways

Initial Injury to 68 Bridges Mostly Due to Failure of Piers and Abutments—Steel Structures, Rigidly Braced, Offered Greatest Resistance to Shock

BY MITSUO NAWA

Engineer, Government Railways of Japan, Tokyo, Japan

FIRE, WHICH was so disastrous a consequence of the earthquake of Sept. 1 in centers of population, did little damage to property of the Government Railways of Japan, except to rolling stock. Most of the damage which spread over an area of 3,270 sq.mi. and made necessary reconstruction of 372 miles of line, was due to the shock itself. In this mileage were included 68 bridges which were injured. Thirty-two tunnels, of a total length of 2,855 ft. also sustained damage. Station buildings which burned included four of brick and thirteen of wood; twenty-two constructed of wood collapsed. An official report lists twenty-two train accidents caused by the quake, 53 locomotives burned or damaged, and 386 passenger cars, 817 freight cars and 31 electric cars burned.

Damage to Bridges—The damage to bridges comprised for the most part the cracking, displacement or complete failure of abutments and piers. Steel girders sustained slight initial damage. Typical of the shock's effect on bridges is what happened to the bridge over the River Banyu on the Tokaido main line. This consisted of two single-track structures each with 28 plate-girder spans 70 ft. long. The piers were of brick and hewn stone piled on elliptical hollow piers known locally as wells. These had a 12-ft. major axis and a 7½-ft. minor axis. Forty-four of these piers were broken at the point near the water line and fell downstream. The wells leaned and some of them shifted off center as much as 2 to 3½ ft.

The bridge over the Sakawa River on the Atami line consisted of eight spans of double-track truss girders 150 ft. long, and two lines of 16 spans single-track plate girders 60 ft. long. The piers for the 150-ft. girders sustained no damage; the girders rested on reinforced-concrete cylindrical wells 14½ ft. in diameter and 30 ft. center to center, and the pier wells, sunk 50 ft. below the river bed, were concrete. Upon them concrete columns faced with masonry were built up to the bridge seat. The damage to this bridge, as shown in the accompanying photograph, was due to vibration, a span of truss girders 150 ft. long becoming unseated.

Considerable damage was sustained by bridges of the older type of construction where piers were connected by masonry arches. Absolute comparison of these structures with newer design was had at the crossing of the River Rokugo on the Tokaido main line. The railway bridge consisted of two lines of five spans of double-track truss girders 120 ft. long and four lines of 24 spans of single-track plate girders 44 ft. long.

At the center an elliptical well with major axis of 21½ ft. and minor axis of 14½ ft. diameter was sunk and on either side a cylindrical well of 14½ ft. diameter on which piers, as in the case of the bridge over the Sakawa, had been separately erected. Of these piers only a single column was broken but slightly downstream on the Tokyo-Yokohama Electric Ry. Co. line all five piers were cracked at a point under the arch, that structure having piers connected by masonry arches.

There were no arch bridges of long span in the district sustaining heavy damage, but in the bridges of short span whether of brick or concrete, side walls were forced out by the lateral pressure and the arch ring was cracked usually longitudinally.

Damage to Embankments—Inasmuch as embankments and reclaimed land offered a very low resistance to shock, some which met the vibration at right angles were cracked longitudinally or wholly broken. In several instances earth and gravel behind abutments subsided, pushing abutments forward or making them lean so that at several points the track was suspended in mid-air. The subsidence of reclaimed land at the stations of Shimosoga and Odawara and at the wharves at Yokohama was remarkable. Due to this subsidence track was often bent vertically or sidewise and the buildings leaned or collapsed.

Landslides Produced—In some districts where severe tremors occurred as in the mountainous part of Hakone,

RAILWAY MAP OF JAPANESE EARTHQUAKE AREA; DAM-
AGE TO GOVERNMENT RAILROADS INDICATED
BY SOLID BLACK LINE

steep mountainsides of rock or earth and sand cracked at several points. Cracks in turn led to permeation of rain water often causing landslides or flows of mud which buried or washed away houses, railways, forests and fields, and otherwise inflicted serious damage. The Hakone mountain ranges which were covered with green before the earthquake, now show many barren patches.

The landslide which brought about the greatest disaster occurred just above Nebukawa station on the Atami line. It carried away the main station building, a passenger train then stopping there, plunging everything into the sea and killing more than 100 persons, including passengers and station staff.

The greatest mud flow occurred also near Nebukawa station, coming down along the upper stream of the River Shiraito and washing away the greater part of a bridge, together with its piers. This bridge was 105 ft. high and consisted of three 140-ft. truss girder spans and four 40-ft. plate-girder spans.

Damage to Tunnels—Greatest damage to tunnels consisted in cracks across the walls near portals produced by earth and gravel above the portal sliding down and pushing out the upper parapet wall. However, in some instances, the interiors of tunnels were damaged, though the damage occurred where there was a fault or where there was softer soil and less surcharge.

Elevated Structures Suffer—The elevated line of the Government Rys. through Tokyo in the downtown district is laid in soft ground. The greater part of the track has been built on arches of brick or reinforced concrete of 26 to 40 ft. spans, the foundation of which was made by driving in pine piles and reinforced-concrete piles about 50 ft. in length. Where the ground is weaker, reinforced-concrete slabs were put in instead of the masonry arches. Further steel plate girders were used over roadways and reinforced-concrete skew arches of 125-ft. span were built over the Sotobori Canal. This elevated line sustained practically no damage from the quake itself, a few plate girders alone being shifted. But as various articles were stored beneath the arches and slabs, these took fire and the inner bricks of the arches were affected by the intense heat losing their coherence and flaking off in thin layers. Fire damage to the slabs seems to have been very slight.

The elevated line at Yokohama was laid upon an embankment. In one section a vertical concrete retaining wall was used on each side and in another section a similar wall was used on the one side and the slope was sodded on the other. The intermediate fillings sank a few feet and the retaining wall either was forced out vertically or leaned slightly forward. Owing, however, to the fact that expansion joints were used at 33-ft. centers, no damage was suffered by the wall at any particular point.

Buildings—The main building at the Tokyo station, a three-story steel-frame structure with brick walls, sustained no damage in spite of its size. The main buildings of Manseibashi, Shimbashi and Yokohama stations were two-story brick structures. They were gutted by fire, but remaining walls show no trace of earthquake damage. The fan-shaped reinforced-concrete engine houses at Shinagawa and Yokohama were built upon reclaimed land and have been cracked at several points, as at beam joints.

The majority of the cast-iron columns supporting the roof over the passenger platforms at Tokyo station were

broken and fell. There were many wooden main buildings, sheds or storehouses which collapsed at local stations, among which may be mentioned the reinforced-concrete freight shed at the Takashima yard.

Rolling Stock—Most of the rolling stock destroyed by fire was lying in the station yards of Ueno, Tokyo, Shiodome, Iidamachi and Akihanohara. Other chief damage to rolling stock was due to derailment caused by the earthquake.

Conclusions—Conclusions to be drawn from minute examination of damaged property are:

1. The extent of damage to works and structures varies with the distance from the seismic center, the topography and the nature of the soil of the locality affected, method and character of construction and material, etc.

2. The resistance to vibration offered by embankments and fills is low so that construction of any high earth dams or of any structures built upon embankments which span both firm and weak strata should be carefully executed.

3. Brick or masonry generally offers low resistance to earthquake shock. In Tokyo some brick buildings of less than five stories suffered no damage, but they were built upon good ground or upon satisfactory foundations.

4. Resistance to earthquake of plain concrete work seems to be nearly the same as that of brickwork.

5. In general, steel structures offer a high resistance to earthquake shock. Steel framed buildings with reinforced-concrete walls have offered excellent resistance to shock. Just below them are steel frame buildings with good brick or hard stone curtain walls. Any buildings having hollow brick or terra cotta curtain walls sustained severe damage and the walls between windows showed large cross-shaped cracks or else the bricks fell out completely. Where bracing was insufficient steel columns were often found bent. It seems that there were not a few steel structures wherein rigidity had not been fully considered, failure consequently resulting.

6. In point of resistance to earthquake, reinforced concrete comes next to steelwork. Generally, also, reinforced concrete proved excellent against fire.

7. Wooden houses, of less than three stories and those roofed with light materials, offer a fairly high resistance to earthquake shock.

Other Comments on Structural Damage

IN A brief letter to *Engineering News-Record* K. Koyanaga, engineer in the Yokohama harbor engineering office of the Japanese Department of Home Affairs, explains that about 3,500 ft. of the breakwater of that harbor sank beneath the low water line. The quay walls, of gravity retaining wall type and constructed principally of large-size concrete blocks, were overturned or shifted, resulting in some cases in complete failure of piers and pier sheds. Many of the sheds were burned.

One of the curious effects of the shock is shown in the view herewith, sent in by Mr. Koyanaga. The statue of Iikamonnokami was turned on its base through an angle of 45 deg., although neither base nor statue was badly damaged.

Several interesting findings regarding earthquake resistance were developed from an examination of buildings in the affected area by Daniel O. Larsen,

FIG. 1—BANYU BRIDGE ON TOKAIDO MAIN LINE
Structure of two single tracks of plate girders completely wrecked through pier failure.

FIG. 3—ARCH CULVERT ON TOKAIDO MAIN LINE

FIG. 5—SHIRAITO BRIDGE ON THE ATAMI LINE
Landslide caused the failure here of two spans of double track (two piers, 150 ft. long, and three 100-ft. spans).

FIG. 2—BRIDGE OVER ROKUGO ON TOKAIDO MAIN LINE
Broken pier supporting end of 129-ft. span.

FIG. 4—BRIDGE OVER SAKAWA ON THE ATAMI LINE
Failure occurred through double track (two piers, span, 150 ft. long, becoming uncoupled and falling on its side).

FIG. 6—SHOCK EFFECT OF A FILL ON ATAMI LINE.

The article by M. Nawa comes in reply to a letter sent its Japanese subscribers by *Engineering News-Record*. On page 1050 are shown photographs supplied by H. Sakakibara, manager for F. C. Kojima, reinforced concrete designers and builders of Tokyo, and by K.

Kagunagi, of the Yokohama harbor engineering office, Department of Home Affairs. Acknowledgment is also made of letter from Ichiro Goto, engineering department, Daiichi Electric Power Co., Nagoya, and from R. Ono, Morioka Eng. office. —EDITOR.

architect, of W. M. Vories & Co. Mr. Larsen's inspection was made in company with several engineers of the Takenaka Co. and the Truscon Steel Co., and covered about thirty modern buildings in Tokyo and Yokohama.

Many of their observations were directed to fire resistance. As to earthquake resistance the following points developed:

Continuous-slab reinforced-concrete foundations stood

the effects of the earthquake in almost every case, whereas buildings with individual spread footings went to pieces. This was illustrated in the Kogyo Bank building, the Imperial Hotel, Mitsubishi building 27, several of the Marunouchi buildings, and others, which show practically no damage.

Exterior walls were not damaged above the sixth floor, even when hollow tile was used. Reinforced-concrete or solid brick curtain walls are necessary up to at least the sixth floor, however. The Kogyo Bank, which shows no damage, has a reinforced-concrete wall up to the third floor and all corners have reinforced-concrete curtain walls; other walls are brick. Another building which shows no damage has solid brick curtain walls.

Solid partitions are favorable to earthquake resistance. Partitions of reinforced concrete or brick running through a building seemed to add noticeably to its resistance. It was also concluded that ceiling heights should be as low as possible.

Exterior finish will crack in proportion to the strength of the structure. Two buildings which had granite finish in the first three stories and terra cotta above, the Nippon Sekan and the Kogyo Bank, were affected differently. The former was seriously damaged by cracking of both the stone and the terra cotta; its frame comprised steel columns incased in brick and hollow tile. The other building had steel columns incased in concrete (and a better foundation) and showed no cracks in the stone or terra cotta.

Conclusions as to earthquake resistance have also been given by R. F. Moss, vice-president of the Truscon Steel Co. of Japan. They are:

1. Floors and roof should be made as light as possible, to reduce the earthquake forces imposed on the walls and columns which carry them.

2. Walls and columns should be proportioned for transmitting the earthquake forces to the whole construction above.

3. Large open floor spaces unsupported by walls and partitions should be avoided, so that sufficient wall and column strength may be available. The Marunouchi building suffered less in the 1923 earthquake than in the much smaller 1922 earthquake; in the interim the

SECTION OF YOKOHAMA QUAY WALL AND PIER

hollow-tile partitions had been replaced by concrete and cement plaster partitions, the columns had been strengthened, and bracing added, the large floor areas thus being divided into small units each supported by strong partitions.

In steel-frame buildings the lateral strength of the steel columns is of secondary importance. Most of the work of transmitting the horizontal earthquake forces to the upper parts of the building must be done by the masonry walls and not by the steel columns. The buildings of the Nippon Oil Co. and the Nippon Yusen Kaisha had unusually strong columns, especially designed to resist earthquakes, but the walls of these buildings suffered more damage than did the walls of the Tokyo Marine Insurance Co. and Marunouchi buildings, which were designed much lighter but had stronger walls.

4. Good workmanship is of primary importance. Well laid stone walls suffered little. The behavior of brick walls seemed to depend on the workmanship and quality of the brick and mortar. Well-built reinforced-concrete walls came through with practically no damage.

5. All parts of the foundation should be connected together by members strong enough to make the various parts act and move together. The partial failure of the fifteenth bank building in Yokohama is chargeable to violation of this requirement. All of the center columns were not connected to the outside walls, and the horizontal displacement of the foundations was not uniform.

6. In tile roofs, every tile should be individually secured so that it cannot slip during an earthquake.

Engineers For Traffic Study

The Philadelphia *Evening Public Ledger* recently commented upon a problem of interest to engineers as follows:

"Mayor-elect Kendrick is wise in assuming that he might begin his administration well by submitting the whole problem of traffic congestion to a Board of Engineers. The traffic problem has been left to run rather wild. The police do their best with the facilities at their disposal, and, all things considered, they do amazingly well. But the pressure of motors in the narrower streets is leading to something like a deadlock.

"Neither automobiles nor trolley cars can move freely during the morning and evening rush hours. Indeed, the streets no longer serve the purpose for which they were intended. Business is being slowed up in many areas. It may be too much to suppose that engineers could find a prompt and easy way out of the dilemma in which the city finds itself. But they could at least lay the foundations of a scheme by which, as we go along, science may be applied to a problem which haphazard methods have failed to solve."

YOKOHAMA STATUE TURNED 15 DEG. ON BASE

Hydraulic Tests of Flap Valves on Drainage Pipe Outlets

Determinations of Angles of Repose and Loss of Head in "Calco Gates"—Head Loss Slight and Leakage Small With Closed Gate

BY PROF. FLOYD A. NAGLER

Department of Hydraulics and Mechanics,
State University of Iowa, Iowa City

GATES of a flap or shutter type are often installed at the outlets of drains serving low-lying lands and tidal marshes. Manufacturers have claimed that such gates offer little or no obstruction to the normal flow of the water in the drains toward the water course since only a small force is required to open the gate. However, when the water in the main water course

FIG. 1—A 30-IN. CALCO FLAP VALVE DISCHARGING 29.8 SEC.-FT. FREELY INTO AIR

risks to flood stages and stands higher than that upon the land itself the gate is forced firmly against its seat preventing the inundation of the land by water from foreign sources.

During November, 1922, experiments were performed at the hydraulic laboratory of the State University of Iowa to determine the actual amount of head lost through gates of this type. Double-hinged cast-iron flap gates of the "Calco" type (manufactured by the California Corrugated Culvert Co.) were secured for these tests, in sizes 18, 24 and 30 in. in diameter. Fig. 1 shows one of these gates operating with free discharge at the outlet.

The loss in head through each gate was observed with outlet velocities of from 1 to 8 ft. per second, while the corrugated pipe to which the gate was attached flowed either partially or entirely full, and with the jet at the outlet discharging freely in the air or entirely submerged.

The gates were attached to the end of a 10- or a 12-ft. length of Armo corrugated-iron pipe of the corresponding diameter in the hydraulic canal. By means of piezometer connections at intervals of 2 ft. throughout the entire length of the pipe, and hook gages installed in the basin above the inlet of the pipe, the hydraulic gradient was observed when the shutter of the gate was raised clear of the jet issuing from the outlet. The gate was then lowered so that it floated in a natural position and the hydraulic gradient was again observed, care being taken that the same quantity of water passed through the outlet as in the first case.

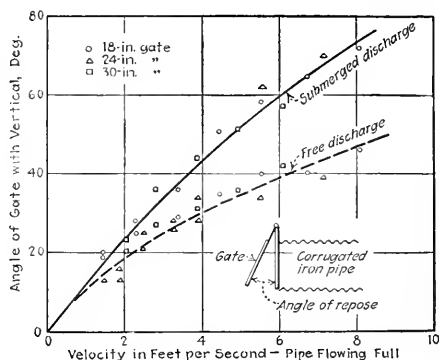

FIG. 2—ANGLE OF REPOSE FOR FLAP VALVES AT VARIOUS FLOW VELOCITIES

The difference in the elevation of the hydraulic gradient at points upstream from the gate was taken as a measure of the loss in head through the gate. The volume of water discharging through the gate was measured by a 5-ft. Bazin weir.

The loss in head caused by a gate of this type is obviously dependent upon the amount of obstruction caused by the shutter, and this in turn is dependent upon the angle at which it hangs. If water flows through the outlet at a high velocity the shutter is forced outward so that it rests almost horizontally, causing but little obstruction to the flow of water from the outlet; but if the water issues at a low velocity the shutter falls to a more nearly vertical position. The angle which the shutter makes with the vertical for the various gates tested was found to be practically identical and is shown graphically in Fig. 2 for the condition of both a free and a submerged outlet. Thus with the outlet flowing full with a mean velocity of 6 ft. per second the shutter rests at an angle with the vertical of 39 deg. if the jet discharges freely into the air, whereas the angle is 60 deg. if the gate is submerged. It proved possible to verify theoretically the results shown by these curves by computing the moment of reaction of the jet issuing from the outlet and equating it to the gravity moment of the shutter.

The loss in head caused by any gate proved to be less than 0.01 ft. under all velocities of flow when the water discharged from the outlet freely into the air. The loss in head with a submerged outlet (Fig. 3) is greater. For all three gates a maximum value was

FIG. 3—LOSS OF HEAD DUE TO FLAP VALVES

reached when the velocities of flow were between 2 and 3 ft. per second, in which case the shutter hung at angles between 23 and 34 deg. with the vertical. The loss of head in all experiments proved small, reaching a maximum of 0.116 ft. for the 30-in. gate.

The 30-in. gate was tested for leakage when firmly held against its seat by backwater in a testing flume. The maximum leakage with heads varying from 1.6 to 4.5 ft. on the center of the gate was 0.015 ft. per second, the quantity decreasing with increase in head because the greater the pressure the more firmly was the flap held against its seat.

It may be concluded from these experiments that the loss of head through a gate of the Calco type is very small indeed and that such gates have but little effect upon the discharging capacity of drainage outlets. Also, if they are kept free from twigs and debris and properly installed, they may be depended upon to stop effectively the inflow of backwater.

Two Trips of Mixer Construct Four-Way Pavement

Fifty-Foot Reinforced-Concrete Park Road Pavement Has Three Longitudinal Construction Joints Doweled Every Three Feet

BY JOHN J. MURPHY

Engineer, Park Department, Boston, Mass.

A 42-FT. concrete road has recently been constructed in four strips on a portion of Commonwealth Boulevard in Boston. This road carries practically all of the traffic between Boston and western Massachusetts and the pavement was made wide and thick and was heavily reinforced. Its construction was remarkably simple, only two trips of the paving mixer being required to build the four 10½-ft. strips. The 4-ft. gutters are granite block and make the road 50 ft. wide between curbs. Altogether 3,300 ft. of road were constructed.

The original road was crushed stone macadam with a Telford base and had a crown varying from 18 to 20 in. This excessive crown kept the motorists in the middle of the road with disastrous results to the central portion. It was decided to reduce this extreme crown

so that the full width of the road could be used with comfort and no danger. Cutting down of the crown to 8 in. was accomplished by excavating at the center of the road and filling at the sides. This was a very difficult task on account of the Telford base, which it was desired to keep intact as a foundation for the new concrete road. It was accomplished with a shallow-cutting steam shovel which loaded into motor trucks. When shaped and rolled the old construction gave for the new concrete road a foundation of Telford and crushed stone with enough sand distributed on the stone to fill the surface voids.

The concrete was 7 in. thick at all points and was a 1:2:4 mix, using washed sand as a fine aggregate and washed gravel ½ in. to 2½ in. for a coarse aggregate. The pavement was divided into four longitudinal strips, each 10 ft. 6 in. in width. These longitudinal strips were laid in alternate pairs. The mixer traveled on the subgrade and laid a strip on each side as it advanced. When the further end of the road was reached, the mixer was brought back and, traveling on the surface of one of the strips already in place and cured, laid the remaining two sections. The concrete was first screeded with a templet of wood, covered with tin, after which it was rolled with a light metal roller and then belted with a canvas belt. After the initial hardening had taken place, the surface was scored with brooms in order to roughen it and afford a better grip for traffic.

As the drawing shows in detail, the road was reinforced with ½-in. square steel rods, 2 ft. 6 in. on centers, both longitudinally and laterally. These rods were all placed in the bottom of the slab. They were made up in mats, all wired together, the transverse rods 10 ft. 2 in. in length, and the longitudinal rods 12 ft. in length. One-half inch square dowels 4 ft. long were placed in the center of each slab, 3 ft. apart, at the transverse and longitudinal joints. One-half of the dowel was left rigid in one slab and the other half was painted with asphalt. A ½-in. square rod 3 ft. long was placed in each corner and at the top of each slab. These corner rods were placed at 45 deg. to the joints. At each transverse joint elastite joint filler ½ in. thick and 8 in. wide was used. The transverse joints were placed 60 ft. apart. The faces of the first concrete strips poured were

TRANSVERSE JOINTS DIVIDE PAVEMENT INTO 10½-FOOT SLABS

SECTION AND REINFORCEMENT PLAN OF FOUR-STRIP CONCRETE ROAD

painted with asphalt before the final two strips were poured. After being placed the concrete was protected by canvas and thoroughly covered with earth, which was kept moist for a period of ten days after laying, when this covering was removed. The road was finally opened for travel two weeks after the last section was poured.

A two-bag paving mixer was used and a day's run consisted of laying two parallel strips each 10 ft. 6 in. wide and 240 ft. in length, totalling 109 cu.yd. Metal forms were used throughout the work.

The road has been banked at one curve and the gradient at this curve is 7 per cent. This required considerable revision of old grades and much excavation in order to change the excessive crown to a banked section.

Boston Park Department to A. G. Tomasello & Son of Boston. The work was started May 10, 1923, and the road was opened for travel August 2, 1923.

Investigates Power on Green River, Wyo.

Recent investigations of the water power resources of tributary streams to the Colorado River by the Department of the Interior have included detailed studies of the possible power site on the largest tributary, the Green River, which has its source in glaciers and glacial lakes on the west coast of the Wind River range near the Continental Divide. The investigations show that probably nine of these lakes, having a combined storage capacity of more than half a million acre-feet of water,

FOUR-STRIP PAVEMENT UNDER CONSTRUCTION

The result obtained is a very even riding surface, the pavement having riding qualities of remarkable excellence. The lowering of the crown, the elimination of crowns and depressions at intersecting streets and the banking of the sharp curve has made this section of the boulevard for its entire width, not only safe against kidding but pleasant to the man who drives a car.

The cost of the concrete road surface was as follows:

Concrete, per sq. yd.,	\$2.71
Steel, per sq. yd., 8 lb. at \$0.652,	11

The cost of the entire improvement was \$74,000.

The contract for the improvement was let by the

may be utilized as reservoirs for irrigation or power generation. The basin of the river above the town of Green River, Wyo., covers about 18,000 sq.mi. of land in the southwestern corner of the state, ranging in elevation from a mile to 13,800 ft. above sea level. Some of this land is already irrigated, and about 400,000 additional acres may be brought under irrigation. The report, which contains maps and photographs, shows the physical features and the meteorological conditions in the basin and describes ten possible power sites. Copies of it are on file in the Geological Survey office in Washington and at the district office of the Survey in Salt Lake City.

Reconstruction of Hell Gate Dam to Eliminate Silt

Silt Deposits from Montana Smelter and Mines Controlled by New Low-Level Sluice Gates—
Replacing Eroded Wall Difficult—Mat Protection Placed in Front of Wall

PONDAGE silt back of the Hell Gate dam of the Missoula, Mont., Light & Water Co., had by 1919 reduced the storage capacity, in the dozen years the hydro-electric plant had been in operation, to such an extent that the peak-load carrying steam auxiliary was being called upon more and more frequently. Four large sluice gates were installed to draw water from the river-bed level in 1919 by means of which the silt

four sluice gates 9 ft. wide and 14 ft. high, at the end nearest the power house where the gates would be accessible and one gate could draw its supply from in front of the trash racks. These gates with their supporting walls took up 53½ ft. of the spillway length, leaving a clear spillway of 220½ ft. Under a normal static head of 31 ft. the gates and the spillway were found ample to take care of flood waters. The gates discharged approximately 13,000 sec.-ft. and proportionally more as the head increased. The spillway under 10-ft. flood discharged approximately 28,000 sec.-ft. The full requirement of the prime movers is 1,600 sec.-ft.

The plans and photographs indicate the general type of construction of the gates. The right-angle turn given the intake for Gate 1 was for the purpose of drawing its supply directly from in front of the trash racks. The upper end of the opening leading to this gate was closed off with a wall built from the top down to within 14 ft. of the floor, thus producing a current at the bottom for clearing silt and debris from in front of the racks. The other three gates draw their supply directly from the pond.

The procedure for wearing down the deposit over the 7-sq.mi. area of the pond contemplated the use of these

FIG. 1—HELL GATE DAM WITH NEW SLUICE GATES AND WALL

Back eddies from discharge several times undermined old crib wall between river and tailrace. Finally new concrete wall was constructed and base rock protected by thick mat of concrete in front of wall.

deposit could be eroded away during flood periods. The concentrated flow and eddy currents from the gates led to serious undermining of a timber crib training wall between the tailrace and the gate discharge. Reconstruction of this wall in three sections was completed early in 1923. The difficulties encountered in maintaining the old crib wall from base erosion, and finally replacing the crib with a concrete wall and mat protection of the rock in front of the wall have kept the operating officials of the power plant and a consulting engineer busy almost continuously for the past three years.

The hydro-electric plant and dam is located just below the confluence of the Hell Gate and Blackfoot Rivers. The Butte copper mines and the Anaconda Copper Mining Co.'s smelter are located 120 miles upstream on the Hell Gate River. Mine-pump and wash-water discharge from these mines, tailings from the smelter together with soil eroded from the bed and banks of the river, nearly displaced the reservoir water capacity. The intakes ahead of the trash racks had become so clogged as to seriously cut down the flow of water to the turbines. In 1919 the company decided to undertake measures for disposing of this silt accumulation and keeping it down.

The mountainous nature of the drainage area above this dam and the heavy snowfall at high elevations result in occasional heavy spring flood discharges of long duration. On one or two occasions the discharge has been known to reach 9 or 10 ft. over the crest of the dam, approximately 35,000 sec.-ft. The dam is of timber construction with a spillway length of 274 ft., the crest of which is fitted with 6-ft. hinged flash gates.

Sluice Gates—It was decided to install in this dam

FIG. 2—CRIB WALL PROTECTED BY SHEET-PILING UNDERMINED

gates at intervals, when the accumulations warrant their use, during high river discharge periods only. The operation of these gates for silt cutting is as fol-

FIG. 3—TIMBER CRIBS AND NEW DIVERSION WALL

lows: Water in the pond is drawn down as quickly as possible to within a few inches of the silted surface, by dropping the hinged flash gates on the dam crest and opening the sluice gates. By manipulating the gates the pond surface can be brought to a ripple or to a high velocity over the silted area which tends to wear down the silted surface. This procedure lowers the head on the prime movers some 6 ft. for the time and during peak-load hours may call for the use of the steam auxiliary.

New Diversion Wall.—Due to the location of the power house so far out in the river it was necessary to construct a diversion wall of some size to separate the tailrace from the river. This wall consisted of timber cribs, bolted together and filled with rock and gravel, and was supposed to rest on rock ledge, although no plans of its construction were on file. The crib had been repaired or rebuilt several times in the past fifteen years. About two years prior to the installation of the gates the second crib based on the native ledge was built alongside the original one on the river side. The new crib was filled with heavy rock, some of which weighed several tons, extending well above the surface.

In locating the gates at the power house end of the dam it was expected that the discharge might eventually dislodge a part of the new crib, although the discharge from the gates, due to the design of the guiding walls below the gates, was partially directed toward the middle of the river. Since the original crib diversion wall was supposed to rest on solid rock it was believed to be reasonably safe.

The first time the gates were used for the spring flood in 1920, their discharge proved to be much more destructive to the base ledge than was expected. The severe return eddies soon tore out the heavy stone protection crib addition last built and began undermining the main original crib. About this time the flood waters subsided and the gates were closed. Later in the year an attempt was made to stay temporarily further undermining, due to the action of the eddies, by driving steel sheetpiling along the river face of the old crib and pouring concrete back of the piles. When the gates were opened the next spring (1921) this sheeting was soon undermined by the ledge disintegrating and letting the water work up under the old crib. The gates were closed and a decision was reached that all further work should be of a permanent nature. As diamond drilling was deemed too expensive, it was

decided to proceed with the work of unwatering the site and then accommodate the designs of the new concrete wall to the conditions found. From soundings the rock was found to be stratified and easily broken, but no knowledge was gained as to the thickness of its strata or its homogeneity. The water depth taken 40 to 50 ft. downstream from the gate apron and 10 ft. out from the old crib was 32 ft., and 4 ft. below the gate apron it was 16 to 21 ft. The old crib had a width of 32 ft., its top was 10 ft. above normal river level and its base 16 to 18 ft. below water level.

The designs called for a wall about 162 ft. long with an 8-ft. base, battered to 5 ft. at the top, and about 30 ft. high, on the assumption that the base ledge was 17 ft. below normal water level. The wall was to be cast in 33-ft. sections, separated by expansion joints and reinforced with steel bars partially for temperature strains but chiefly for surface protection from the pounding of logs. Due to the probability that the underlying ledge would prove insufficiently hard to resist the wearing action of the water, the original designs of the wall contemplated the use of reinforced

FIG. 4—NEW CONCRETE WALL WITH BASE PROTECTION

precast concrete piles 10 in. in diameter, varying in length from 8 to 14 ft. and spaced 6 to 8 ft. on centers, located on the river side of the center line of the wall base. Holes 12 in. in diameter were to be drilled in the base ledge and the piles dropped and grouted into

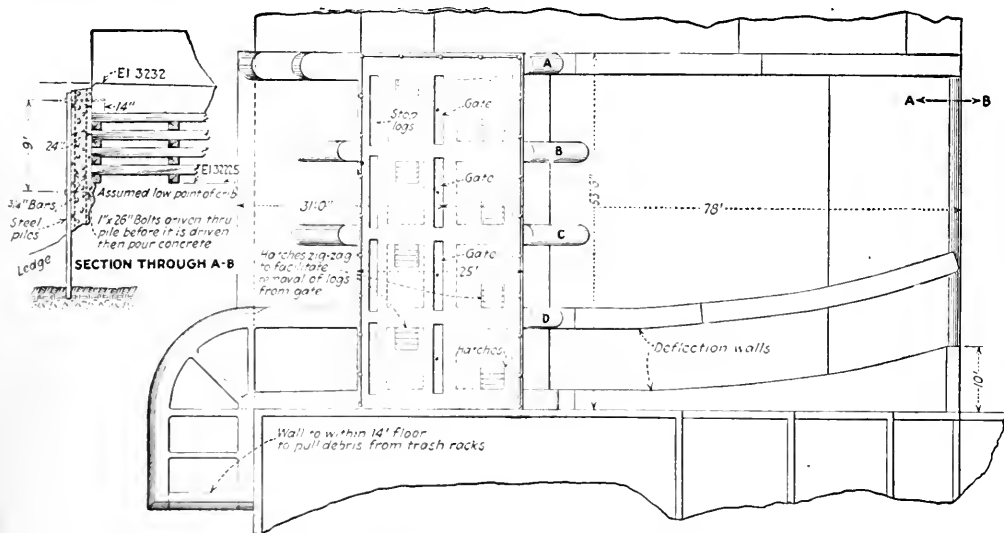

FIG. 5—NEW SLUICE GATES IN HELL GATE DAM

place, their function being to support the wall in case of partial undermining. Conditions at that time indicated that the river side of the wall base would be located about 8 ft. back from the edge of the rock ledge sloping rapidly downward toward the river. Should the rock prove to be of a nature easily disintegrated, the piles would render the wall stable until a concrete facing against the base ledge could be laid. The plan of using the piles was found to be impractical. No drilling in the base rock was done, but cores were

In the building of the new wall, three serious factors in its construction could be anticipated: (1) The old crib was in the way. (2) It was sure to be difficult to get through the crib to the base rock and exclude the water in the meantime. (3) Security must be provided against further underwash after the wall was completed.

The first section of the new wall was started about 50 ft. downstream from the end of the dam apron. The old crib at this point was torn down to river level.

FIG. 6—SECTIONAL ELEVATION THROUGH NEW SLUICeway

provided in the wall itself from base to top, through which at a later date, if necessary, drill holes could be made and the piles used.

The steel caisson was now started, using 14-in., 42-lb. steel piling, driven with a heavy steam hammer. On the tailrace side of the old crib, this piling was driven

in the open water outside of the crib. On the river side of the crib and at the two ends of the caisson it was driven through the crib timbers, bolts, rocks and slabs of concrete. Much of the piling had to be withdrawn in a badly battered and twisted condition and repaired, greatly retarding the work. One 10-in. horizontal-shaft and one 6-in. vertical-shaft pump were installed, driven by 75- and 50-hp. motors, respectively. As the driving and excavation proceeded it was found necessary to drive another row of sheetpiling on the river side, outside of the old crib. This added resistance to the water for the time enabled the pumps to keep the water down inside the caisson.

This first section of wall was hardly completed when a flood came down and the gates were opened for a few days. Before the flood subsided it was discovered that the base ledge had been eroded up to and immediately under the new wall section. The gates were closed.

The second (down-river) section of wall was now undertaken. When excavation had reached a point about 10 ft. below water level, leakage under the two courses of caisson steel piling on the river side became so great that the pumping capacity was inadequate, and about 1,000 cu.yd. of gravel was deposited on this side which greatly improved the situation, until the second section was finished.

For the third and longest (up-river) section the progress was slow and tedious, due chiefly to slabs of old concrete 2 to 10 ft. in thickness imbedded in the old crib. It was too close to the power house and dam to permit the use of explosives, consequently "bull points" and picks were used in wearing down the old slabs, which slowed up the work. Little difficulty was experienced with water.

For protection of the base ledge from erosion a concrete mat was laid under water along the base of the wall as a permanent protection. The bedrock was first thoroughly cleaned with a clamshell bucket and a high-pressure water jet. A wall of steel sheetpiling was anchored 20 ft. out from the wall for shutting out all river currents and stilling the water for submerged concrete casting. A wall of sand-filled bags 3 ft. high was laid 15 ft. out from the concrete wall to stop the outward flow of concrete. A mixture of 1½ per cent calcium chloride was used with the cement to hasten its initial set. The concrete was heated to a high degree and a tremie was used for deposition, as the depth of water varied from 18 to 32 ft. Work was commenced at the upstream end so that the laps, if any, would lie with the direction of the water eddies, and was prosecuted vigorously day and night until finished. This mat averaged 5½ ft. thick at the base of the wall and from 3½ to 4 ft. thick 15 ft. out. It was tied to the wall by reinforcing bars previously cast in the wall for this purpose.

The work was done by the Missoula Light & Water Co., of Missoula, Mont., for which C. H. Christensen is general manager. The gates were installed under the field superintendence of H. L. Eickenbach, superintendent of street railways, Missoula. The concrete wall construction was superintended by John A. Hedlund, of Minneapolis, and Mr. Huwe, power station superintendent, rendered valuable assistance through his familiarity with the old structures. The gates and wall were designed by the Power Engineering Co., consulting engineers, Minneapolis, and all construction procedure was carried out under their instructions.

Why Reclamation Costs Differ from Original Estimates

Facts Suppressed in Secretary Work's Comparison of Estimated and Present Costs—Projects Extended on Plea of Land Owners

IN A PARALLEL-COLUMN statement of original estimated cost and construction cost to the present year of the various federal reclamation projects, just issued by Secretary Work of the Department of the Interior, present costs are shown to be far in excess of the original estimate. The statement implies that engineering planning and management of reclamation have been grossly at fault. Inquiries directed to competent authorities indicate that the statement is seriously misleading, and that it suppresses facts which are essential to a proper understanding of the cost figures. The facts as to cost are therefore briefly reviewed here, on the basis of what these authorities have said.

Secretary Work's entire statement is based upon the assumption, which he uses throughout and evidently intends the reader to believe, that the original estimated cost is for the identical structures included in the column of net construction cost. This is not true in the case of any project.

Originally the Reclamation Act was intended to apply to the construction only of such projects and features or parts of projects as were too expensive and difficult for private enterprise. It was assumed and generally promised that the projects benefited by the construction of such large features as reservoirs and main canals would build their own canal systems and distribution systems.

In many instances they already had these systems, and enlargement and extension to adapt them to the new conditions were to be made by the water users themselves. In some cases this was made a specific requirement of the contract. It was found that the water users were unable or unwilling to carry out the extensions and enlargements expected of them or even to acquire title to the canal systems which were necessary for utilization of the water. Under these circumstances the government was requested to undertake large additional work, and did so, with the approval of the Secretary of the Interior and sometimes by his own initiative.

The Salt River project is a typical case in point. In this case Secretary Work lists the original estimated cost at \$5,650,000 and the net construction cost to June 30, 1923, as \$10,548,119.28. The figure given for estimated cost is questionable. The estimated cost of the Roosevelt dam as built was \$3,850,000 and it was built for about this amount. This was the only structure originally contemplated. The valley had a large number of canals which, though poorly constructed and badly maintained, could be used for the delivery of water to the lands already cultivated, and the people were supposed to be able, when a reliable water supply was secured by the reservoir, to improve, enlarge, and extend the canals to the new lands. But while the Roosevelt dam was under construction a great flood washed out the water users' diversion dam 40 mi. below, and the water users being unable to finance its reconstruction, made urgent appeals to Secretary Hitchcock to rebuild it and offered to co-operate in acquiring canals that could use it. Of his own motion, without recommendation from the Reclamation Service, Secre-

tary Hitchcock determined to purchase the canal systems dependent on this dam and rebuild the dam and enlarge and extend the canal systems.

The contract for the reservoir had been drawn in such way as to cover any work the Service might do, and give the Secretary of the Interior the authority to determine the cost, and the water users' association on its part was required to contract to repay to the government such part of the construction cost as the Secretary should assess against its shareholders, thus leaving him in a position to take in some public land and assess a portion of the cost to that and the balance to the private lands which were in the association. This proviso was made the basis of contract on practically all of the early projects, and under it additional work often was taken up, on urgent and persistent pressure from the project people, without a new contract. The various systems of canals in Salt River Valley were purchased for cash and greatly enlarged, improved, and extended to cover new lands.

The original estimate included only the storage works, which were all that were contemplated at the time the project was undertaken. According to the 11th annual report of the Reclamation Service, page 51, these have cost \$3,802,897.06, while the other expenses, not included in the original estimate, but built on urgent requests from the water users' association and landowners, amount to 6 or 7 millions and include the following items:

Power system	\$2,491,593.04
Granite Reef diversion dam	622,784.04
North side canal system, construction	1,102,005.52
South side canal system, construction	696,541.03
Pumping plants	126,548.64
Real estate purchased	32,028.05
Telephone system, construction and betterments	68,892.49
Roads, construction and maintenance	603,941.03

Yet Secretary Work's statement carries the impression, as it evidently is intended to carry it, that the same works that were estimated to cost \$5,650,000 have really cost about double this amount. This is absolutely false.

All the other projects are similarly affected. On two of those projects, the Boise and the Yuma, this identical question has been the subject of protracted and hard-fought litigation, and in both cases the court was convinced that statement of the original cost did not apply to the project that was built because of the great extensions made. For example, on the Boise project, the Arrowrock Dam was not contemplated and never mentioned; in fact, it was not even conceived at the time the contract was entered into with the water users and the canals were built. But it was built as an extension at the urgent request of the water users, who made strenuous efforts to secure the largest reservoir they could induce the government to build. On the Yuma project, the result of the litigation was exactly the same. These two lawsuits occupy such a large portion of the files, in correspondence, briefs, and decisions which were handed down, that it would be impossible for any one examining the files of the Service to overlook them.

The Salt River case and the Uncompahgre case have been so much discussed and the files contain such complete statements that it is equally impossible for the real facts to have been overlooked in these cases. The

additional work on the Salt River project was dealt with in the public hearings in 1913, and presented in Congressional hearings at a later date.

In the later years, with the approval of Congress, on a large number of projects drainage works have been carried out which were never contemplated in the original estimates.

As time passed, however, the Reclamation Service learned that those upon the projects desiring to escape their payments were prone to use the same words that Secretary Work has here used to deceive the public by speaking of the original estimates of the "project" and the ultimate cost of the "project" as though they applied to the same works and the identical project, using this argument to prove waste and to discredit the Service and thus escape their payments. Partly for this reason the policy was adopted of requiring a new contract for each additional feature the government was requested to undertake, so that in many cases the additional work is represented by separate, additional contracts. This statement would apply to more than half of the projects. The new work being represented by different contracts, it can not be confused with the works contemplated by the original contract; but Secretary Work's statement does so.

Statements of discrepancies between the estimated and the actual costs widely published by an official as high in responsibility as the Secretary of the Interior (and attributed at least by implication to extravagance, waste, and graft) will encourage those who advocate repudiation of payments. It will tend to diminish the chances of recovery of the cost of the projects.

The Secretary says in his statement on costs: "This intensive study of reclamation as a business is the first ever made. It should have been made ten years ago." The fact is that the Reclamation Service has been under investigation nearly half the time since it began operations, by several Congressional committees, including the Appropriations Committee, and many inspectors from the Secretary's office and from the Treasury Department. In 1910 it was thoroughly investigated by a board of army engineers, which among other things reported that "In its inspection the Board was impressed with the ability of the employees occupying positions of responsibility and desires to record its appreciation of the assistance rendered by them." The most exhaustive examination of all was made by a series of boards of review instituted by Secretary Lane in 1914. Reports by these boards were passed upon by a central board of review consisting of Dr. Elwood Mead of the University of California, Gen. W. L. Marshall, ex-Chief of Engineers, U. S. A., and I. D. O'Donnell, a successful irrigation farmer. Nearly a year was spent in this investigation, and it eliminated two items of cost charged on the books, one from the Salt River project and one from the Uncompahgre project. Yet, in spite of this adjudication, the Secretary asks for authority to reopen all these cases and "make adjustments" between the government and the projects.

Strength of Limestone in Tension

Tension tests on samples of Indiana limestone recently made at the Bureau of Standards, in connection with the design of lifting devices for hoisting large blocks of stone, showed values ranging from 300 to 715 lb. with an average of 535 lb per square inch.

Chicago Heavy-Traffic Street Tests Asphalt Mixtures

**Stiff Mixture Stands Up Under Traffic of 16,000
Vehicles a Day While Softer Mixture
Ruts and Rolls Badly**

BY HUGH W. SKIDMORE

Consulting Engineer, Chicago Paving Laboratory, Chicago, Ill.

TWO distinct mixture designs were employed in street asphalt pavement laid on Michigan Boulevard in Chicago, in 1919 and in 1920. One design failed and the other was a success. As the comparison was unusually fair, these results warrant analysis. Also the conditions represent about the maximum of density of street traffic—that of the famous "link" over the Chicago River and connecting "north" and "south" Michigan Avenue.

Both traffic and foundation conditions are identical over the entire length of this pavement. The traffic is fully as dense as on any pavement in the world. As high as 60,000 vehicles per day pass over the pavement. These are by no means all swift-moving pleasure cars;

TWO TYPES OF FAILURE—RUTS AND WAVES

Note the seriousness of these waves, also the ruts toward the center in the line of travel of light vehicles. The mixture plainly shows its excess of bitumen.

a large number of heavy motor buses ply back and forth night and day. The former tends to roll or wave the pavement transversely, while the latter tend to form longitudinal ruts in the surface. Both of these types of defect are very much in evidence in that portion of this pavement which was laid in the spring and early summer of 1920.

A comparatively small portion of the pavement being considered was laid in the late summer and fall of 1919. The wearing surface mixture was especially designed to overcome any tendency toward distortion under traffic. The mixture was designed for a maximum density, comparatively "dry," i.e., with absolutely no excess of bitumen, and with what was considered by some entirely too much mineral filler. The penetration of the asphalt cement was set as low as was considered entirely safe from the standpoint of cracking, viz., 30 to 35. An analysis of the mixture was as follows:

	Per Cent
Bitumen, by weight	10.6
Mineral passing 200	18.0
Mineral passing 80	26.8
Mineral passing 40	31.7
Mineral passing 10	10.7
Mineral passing 4	2.2
Penetration at 77 deg. F.	33

The maximum amount of bitumen in a large number of samples tested was 10.8 per cent and the minimum was 10.1 per cent; the majority showed about 10.5 per cent. The minimum of filler passing the 200-mesh screen in these samples was 17 per cent while the maximum was 20 per cent; the maximum penetration was 35 and the minimum 31.

No rutting has developed in this portion of the pavement, and the only evidence of any forward displacement occurs to a slight extent at a corner where the heavy motor buses have come to a sudden stop, on a slight down-grade. Even this is as yet of minor consequence and is thoroughly localized. No cracks have occurred, except in one or two instances of surface reproduction of contraction cracks of portland cement concrete base, which appeared during the first winter. It is altogether possible that these also might have been largely overcome by traffic, were it not for the fact that this portion of the work was closed against traffic during the first few months after it was laid. One of the most striking and significant things in this entire stretch of pavement is the joint between the work laid in 1919 and 1920. The softer mixture of 1920 can plainly be seen rolling down over the more stable 1919 work.

The character of mixture laid in 1920 is radically different from that of 1919 in two fundamentals; first it carries on the average more than 10 per cent more bitumen by weight, i.e., where the 1919 contained an average of 10.6 per cent, the 1920 mixture showed an average of 11.7 per cent; second, the average penetration of the asphalt cement used in 1920 was over 40, in fact ranged from 36 to 46 with the average at 41. Also the average amount of 200-mesh filler was slightly less than in 1919. All of these things combined to produce a much softer and consequently much less stable mixture than was produced by the 1919 design. The great increase in bitumen content was undoubtedly the principal factor. An average analysis follows:

	Per Cent
Bitumen, by weight	11.7
Mineral passing 200	17.0
Mineral passing 80	27.5
Mineral passing 40	35.2
Mineral passing 10	8.1
Mineral passing 4	0.5
Penetration at 77 deg. F.	41

Numerous samples showed more than 12 per cent and one more than 13 per cent bitumen; and in several samples the content of 200-mesh mineral was 12 to 14 per cent. The variation in these two very important items was much wider than in 1919.

To the careful student of asphalt mixtures, it will be immediately apparent that 12 per cent is entirely too much bitumen for such a severe traffic condition, regardless of the penetration. The low penetration of the asphalt will not cure the tendency to distort under traffic, unless it is accompanied by a proper relation between fine mineral and bitumen. Low penetration in such cases most certainly assists, but it does not alone accomplish the result, in fact it is considerably secondary to the bitumen content in its relation to the filler. During recent extensive repairs to the section laid in 1920, pieces of the original pavement plainly showed an excess of bitumen.

It is not known why the radical departure from the 1919 design was made. Possibly some official may have been unduly alarmed at the foundation cracks which appeared during the winter of 1919-1920, think-

ing the asphalt was too hard. It is now certain that the change which was made spoke failure for the altered type of mixture. It is also of interest to know that this failure was predicted by those who were most instrumental in the design of the 1919 work. Signs of the coming rutting and rolling were evident only a few months after the pavement was completed.

There is no question but that the real predominant cause of the extensive rolling and rutting of the 1920 work is the very decided excess of bitumen in the sheet mixture, assisted by a penetration which was at least 10 points higher than it should have been. Bitumen content of not to exceed 10.5 per cent accompanied by a filler content of from 16 to 22 per cent would have prevented this disturbance. The movement of this pavement has been confined to the sheet top, at least in the beginning, and until waves were sufficient to produce an ever-increasing impact sufficient to distort the binder course as well as the top. During the recent repair work, the old pavement from a number of the badly affected areas was carefully examined and no evidence of binder movement could be noted.

Many large cities have examples of pavement disturbance under dense traffic. The remedy is an easy one, but it must divorce entirely the old ideas of asphalt mixtures that were in vogue before the day of extensive motor traffic. The standard sheet asphalt specifications of the city of Chicago have for many years called for 11 to 13.5 per cent of bitumen, with a maximum of 15 per cent of mineral passing the 200-mesh screen Michigan Avenue is only one of several examples of failures that will continue, unless the standards undergo a very decided change.

Truss Maintains Equilibrium in Load on Footings

Load Carried to New Outside Columns for Wide Opening—Transferred Back to Old Footings by Truss

BY CHARLES CARSWELL
Philadelphia, Pa.

AN UNUSUAL structural problem, involving the removal in the first two stories of the intermediate columns of one bent, and the transfer of the loads the columns had supported through a new system of steel work to the same foundation on which the columns had rested, is a feature of alterations now being completed on the office building formerly known as the Penn Square Building in Philadelphia. These alterations are part of the extensive changes being made in the building including the addition of two stories, the construction of an entire new front, and interior alterations to link up the building with the Finance Building, adjacent to it on the west, of which the altered structure becomes a part.

The Penn Square Building was a twelve-story structure, built in 1900, and first known as the Levy Building. The two new stories are added without any extensive alteration of the old steelwork, a feature made possible by a change in the building requirements of the city of Philadelphia. The old building was designed for a live-load of 100 lb. per square foot, whereas the present requirement as established by the law of 1919 is for 60 lb. per square foot. The possible increase of load under this condition is therefore about 480 lb. per

square foot, which would be approximately equivalent to the load requirements for three floors. The present design is based upon a dead-load of 95 lb. and the live-load of 60 lb. per square foot for all floors from the second to the fourteenth; the first floor is designed for 110 lb. dead load and 120-lb. live load per square foot.

The frontage of the building is 36 ft. 1 in., and its framework comprises wall columns and two intermediate

FIG. 1. PART PLAN AND SECTION

rows of columns inside the building, making four columns to each bent. The interior columns are spaced 11 ft. $\frac{1}{2}$ in. apart, and are symmetrical about the center line of the building, except in the second bent. In this particular bent the same arrangement is followed above the second floor level, but in order to secure a better arrangement of store space in the first floor, the two interior columns, in the basement and first tier, were each set 2 ft. nearer the center line of the building, making them 7 ft. $\frac{1}{2}$ in. apart. At the second floor level,

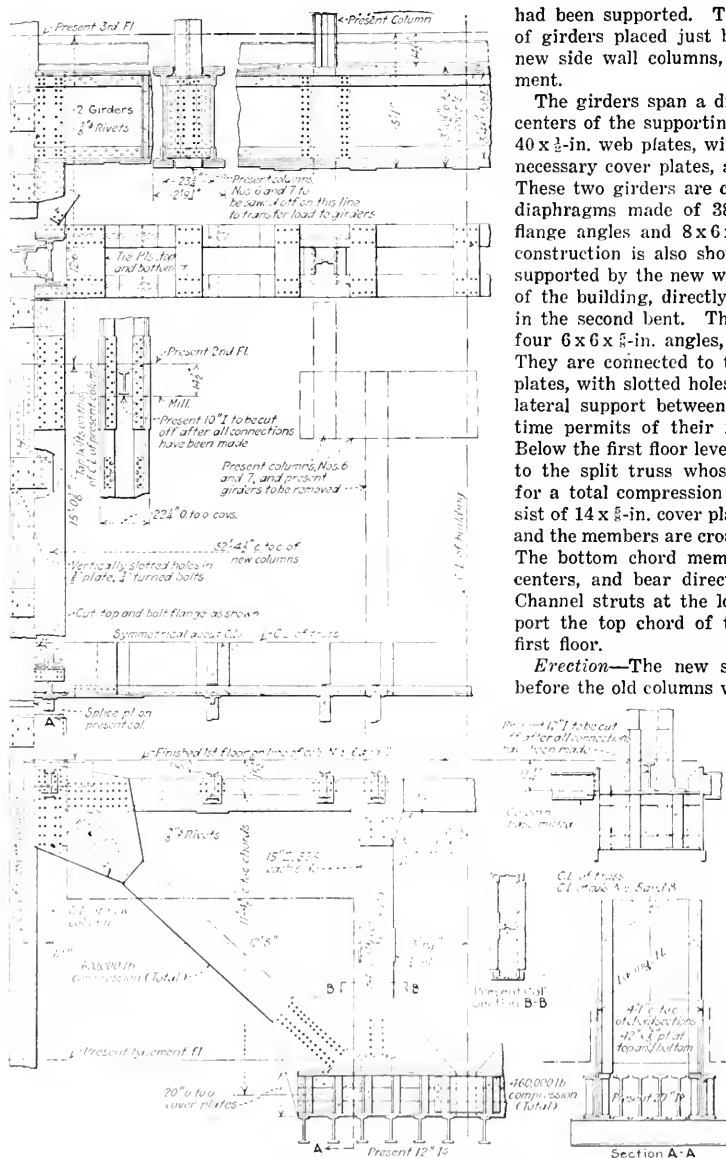

FIG. 2—DETAILS OF THE COLUMNS, TRUSS AND GIRDERS

a girder was connected to the tops of these two columns, and extended out on each side to support the upper tiers at the 11 ft. $\frac{1}{2}$ in. spacing.

In the remodeling it was desired to do away with the second floor in the front portion of the building from the front wall to the third bent of columns. This requirement made necessary the removal of the intermediate columns of the second bent up to the third floor, and for this purpose a system of steelwork was designed to support the columns above that level and to carry the loads to the same foundation on which the columns

had been supported. The steelwork consists of a pair of girders placed just below the third floor lever, two new side wall columns, and a split truss in the basement.

The girders span a distance of 32 ft. $\frac{1}{2}$ in. between centers of the supporting columns, and are composed of 40 x $\frac{1}{2}$ -in. web plates, with 6 x 4 x $\frac{1}{2}$ -in. flange angles and necessary cover plates, as noted in the detail of Fig. 2. These two girders are connected to the old columns by diaphragms made of 38 x $\frac{1}{2}$ -in. plates with 4 x 4 x $\frac{1}{2}$ -in. flange angles and 8 x 6 x $\frac{1}{2}$ -in. connection angles. This construction is also shown in Fig. 2. The girders are supported by the new wall columns placed on the inside of the building, directly alongside the old wall columns in the second bent. The columns have 20 x $\frac{1}{2}$ -in. webs, four 6 x 6 x $\frac{1}{2}$ -in. angles, and two 14 x $\frac{1}{2}$ -in. cover plates. They are connected to the old columns by $\frac{1}{2}$ -in. batten plates, with slotted holes. This type connection secures lateral support between the columns, and at the same time permits of their independent action as columns. Below the first floor level the new columns are connected to the split truss whose diagonal struts are designed for a total compression of 620,000 lb. They each consist of 14 x $\frac{1}{2}$ -in. cover plates with two 6 x 6 x $\frac{1}{2}$ -in. angles, and the members are cross-laced with 3 x 3 x $\frac{1}{2}$ -in. angles. The bottom chord members are spaced 4 ft. 1 in. on centers, and bear directly on the old column grillage. Channel struts at the location of the old columns support the top chord of the truss and the loads of the first floor.

Erection—The new steelwork was erected complete before the old columns were removed. The truss in the

basement was erected first, and the new side wall columns were then erected on it and connected to the old columns. The diaphragms for connecting the columns to the girders at the third floor, were next riveted in place on the old columns. The two girders were brought in on the second floor of the building through the windows and riveted to the diaphragms and to the new side wall columns. These connections made the new steelwork complete, ready to support the column loads. The old columns were sawed off at the bottom of the new girders, sawing being used instead of burning in order to transfer the load gradually.

When the supporting steelwork was in place, the floor beams of the second floor were removed. Removal of these beams made too great an unsupported length in the intermediate columns of the front wall so they were each reinforced by a new section composed of two channels extending from above the first floor to the bottom of the third floor steel, and placed on the inside of the old columns and riveted by $\frac{1}{2}$ -in. batten plates.

The building is owned by the Finance Company of Pennsylvania. The architects are the Hoffman-Henon Co. of Philadelphia, and Percival M. Sax is engineer.

Precast Concrete Units Used for English Footbridge

IN THE recent rebuilding of a footbridge over the tracks at a country station of the Southern Ry., England, a novel design consisting of precast concrete units was adopted. This is shown in the accompanying view. The two 38½-ft. girders have their 7½-ft. end panels inclined downward to carry stairways, and the girders are seated on four-post braced towers, the tops of which form landings for stairways parallel with the tracks. Floor beams fit into sockets on the

FOOTBRIDGE BUILT OF CONCRETE UNITS

Above: Locomotive crane erecting one of the 38½-ft. girders. Below: completed structure.

bottom chords of the girders and upon these are laid the floor slabs. The lower stairway girders rest on the towers and the stairs rest on the lower chords of these girders. The units were made at Exeter, where the railway has a yard for the manufacture of various concrete articles. All the girders were cast on their sides. The units were erected by a locomotive crane.

Demolition of the old wooden bridge was commenced at midnight on a Saturday and completed by 6 a.m. next morning. The erection of the towers, girders, stairs and other parts was interrupted occasionally by the necessity of clearing the tracks for trains, but the entire work was completed by 7 p.m., except for the grouting of some connections. The cost is said to be less than that for a steel structure, even including the forms, which will be used for similar bridges.

The designs were prepared under the direction of A. W. Szlumper, chief engineer, and the structure is described in the *Railway Gazette*, London, by W. H. Shortt, district engineer.

Sightly Construction Gallery Protects Sidewalk in Chicago

THE UNUSUALLY elaborate sidewalk gallery shown in the accompanying view is not a permanent arcade but is erected simply for the convenience and protection of the public during the construction of the 32-story

FIG. 1—SIDEWALK GALLERY AT STRAUS BUILDING, CHICAGO

Straus Building at Jackson St. and Michigan Ave., Chicago. Since it was felt by S. W. Straus & Co., the owners of the building, that the usual rough timber gallery or shelter would not be in harmony with the building or its surroundings, the architects were instructed to provide a sufficiently artistic structure and the design was submitted to the South Park Commissioners for consideration. Arches and ornamental railings are placed in the openings between the posts which support the working deck over the sidewalk, and an

FIG. 2—STRUCTURAL DESIGN OF SIDEWALK GALLERY

FIG. 3—ORNAMENTAL FEATURES OF GALLERY

ornamental parapet surrounds this deck. The structure is painted in two shades of light buff or stone color, and on each street face there is a large panel with a reproduction of the architect's design for the completed building. At first the floor was above the sidewalk level and was reached by two steps, but this floor was removed after completion of the permanent sidewalk.

In its structural design, shown in Figs. 2 and 3, the gallery consists of two rows of 8x8-in. posts spaced 8½ ft. c. to c. on the Jackson St. side and 16½ ft. for the wider Michigan Ave. sidewalk. Longitudinally the spacing is about 8½ ft. c. to c., with archway openings of 6 ft. clear width, but at the corner and at the contractor's driveway entrances the clear width is 15 ft. On the Michigan Ave. side the posts carry two lines of 8x12-in. stringers on which are transverse 4x12-in. joists spaced 10 in. c. to c., but on the Jackson St. side the posts carry 8x12-in. transverse caps with longitudinal joists of the same size and spacing as above. Knee braces are attached to the joists in the former case and to the caps in the latter. The deck which slopes down towards the building, consists of two courses of 1-in. boards with a layer of roofing paper between them and 2-in. plank battens on top. The posts rest on 8x10-in. sills carrying 2x10-in. joists, 18 in. c. to c., with a single layer of 2-in. plank to form the sidewalk. The 42-in. parapet has four rows of 1-in. boards, with braces at intervals. Sheathing is applied to the posts and under the joists.

This structure is designed for a live-load of 500 lb. per square foot on the working deck. Although the design might appear to be somewhat expensive for a temporary structure, the cost was found to be only slightly greater than that for an ordinary rough and

Hints that Cut Cost and Time

unpainted shelter or gallery. The general contractor is the Thompson-Starrett Co., and the architects are Graham, Anderson, Probst & White, Chicago.

Device Removes Sand from Gravel Wells

BY C. K. CALVERT

Assistant Sanitary Engineer, Sewage Disposal Plant,
Indianapolis, Ind.

IN FINISHING wells which will supply water for the new sewage disposal plant at Indianapolis the old air-lift idea to clear them of sand was used but the operators became disgusted with the hand-operated discharge valve and a home-made automatic control was devised. Condenser water for the main power plant of the disposal works is to be supplied mainly from these gravel wells on account of the low temperature of the water. Since it will be used in surface condensers, it must be reasonably free from sand.

The sand is removed by air-lift as follows: When the pump pit excavation is completed, an air-lift is installed with its discharge passing through a special flange which makes the casing head airtight so that pressure may be built up and held in the casing. Air is delivered to the ejector head continuously. Manipulation of a valve on the discharge line causes periods of pressure to alternate with periods of pumping. The pressure forces water and air through the screen, dislodging and agitating the sand and gravel, and on release the water rushes back into the casing, carrying sand which the air-lift discharges with the water. The sand so removed is replaced by gravel piled around the casing on the excavation floor and is replenished after settling.

Extensive tests determined the optimum duration of pressure and pumping periods. Operation of the ordinary gate valve on the air-lift discharge line is time consuming, and a quick-opening valve was substituted. As hand operation was erratic and not dependable, the

FIG. 1—HOME-MADE VALVE CONTROLLER
Bucket on right end of lever arm up and receiving a portion of water from sand tank.

From Job and Office

For Contractor and Engineer

automatic valve control shown in the illustration was devised to reduce the time of sand pumping and eliminate the cost of an operator.

On starting the air-lift, the mechanism is in the position shown in Fig. 1, the counterweight on the left of the arm is down. This holds the water bucket on the right up and in position to receive water from the sand tank overflow. The rod on the right end of the arm holds the air-lift discharge valve open.

Water now flows through the sand-tank overflow line, a controlled part of it going to the water bucket. When the counterweight is overbalanced, the water bucket falls, clearing the stream of water which filled it, and closing the air-lift discharge valve. During this period the water and air rush out of the casing through the screen and disturb the sand and gravel. This position, shown in Fig. 2, is maintained until the water in the bucket runs out through a bottom valve. In this position the air pressure is released, the water, carrying the fine sand, rushes back through the screen into the casing and is raised to the sand tank by the air-lift. The operations are repeated as long as air is supplied to the air-lift.

By manipulation of the valve into and out of the water bucket, the time of filling and emptying, and consequently the period of pumping and pressure on the well, may be varied widely. When adjusted to any rate, the operation is constant and needs little attention.

The sand tank is baffled and provided with a cone bottom which facilitates sand removal. It is usually removed and measured once in 24 hours.

The installation has proved satisfactory. It clears the well of sand in the shortest possible time and gives an opportunity to observe the rate of sand removal and its total volume.

FIG. 2—SECOND POSITION OF VALVE CONTROLLER
Bucket full descends and angle coupling diverts discharge away from bucket. Rate of flow from pipe in side of bucket near bottom determines the interval before light-colored bucket (left) and counterweight lifts empty bucket and opens valve.

How Dynamite Is Used in Ice Blasting

BY N. D. RAND

Technical Division, Atlas Powder Co.

DURING THE winter months ice forms so quickly that at times shipping is bottled up. To relieve icebound boats a channel must be opened and the most practical and quickest way, as well as the least expensive, is to blast the channel out with explosives.

There are two methods of opening up a channel: (1) by placing light charges along the edge of the ice the width of the desired channel and (2) by placing charges along the center line of the channel. The former will break the ice into small cakes, and the latter must contain charges heavy enough to break the ice the entire width of the channel. An experiment in both methods will determine which is the better for the particular conditions encountered.

In order to open a channel holes should be cut through the ice with an ice spud, a splicer bar, or a crowbar. These holes should be from 6 in. to 1 ft. in diameter and cut through the ice to the water beneath.

A good blast does not throw ice and water high up into the air. If that happens, the next charge should either be decreased or lowered further into the water. Distance apart at which to place holes can be determined from the area broken, though the usual distance is from 15 to 25 ft. If there is a current sufficient to carry out the ice charges may be so placed as to break the ice into large cakes. Where no appreciable current exists, ice must be broken into small sizes.

In preparing a charge a rule-of-thumb method which will be successful calls for the use of three times as many cartridges as the thickness of the ice is in feet, and a depth below the ice of one-twelfth of the diameter of the area to be broken. The required number of cartridges should be tied together after having primed one with a waterproof electric blasting cap and smeared a waterproofing compound over the hole where the cap enters the cartridge in order to exclude water from the powder. The cord used to tie the cartridges together should have a free end long enough to lower the charge to the required depth. To hold the charge at the proper depth, tie the free end of the cord to a stick of wood placed across the top of the hole. Dependence should not be placed upon electric blasting cap wires to hold the charge in place. The following table indicates the quantity of explosive to be used and the depth under the ice at which it should be placed for best results in ice of varying thicknesses:

TABLE OF CHARGES

Thickness of Ice in Feet	Number of Cartridges of 40 lb. Gelatin Dynamite	Depth Below Ice in Feet	Diameter of Area Broken in Feet
1	3	1	20
1	3	2	25
1½	4	3	30
2	6	4	50
3	10	5	60
4	20	6	70

Charges should be fired electrically as it enables several charges to be fired at the same time, the combined force of which will break up more ice than if each charge is fired independently.

Large cakes of floating ice may be broken by laying a large charge of dynamite on top of the cake and priming with cap and fuse. The amount of the charge may be determined after a few trials, starting with one or two cartridges. The following table shows the approximate number of 1½x8-in. cartridges of 40 per

cent strength necessary to break cakes of varying thicknesses:

Thickness of Ice in Feet	Number of Cartridges
1	1
1 1/2	2
2	4
2 1/2	6
3	8
	10

If it is impossible or unsafe to get on the large cake of ice in order to place the explosive, the dynamite may be tied to a stone or stick of wood, the fuse lighted and the charge thrown upon the cake of ice in such a manner that it will land as near the center as possible. Such charges are primed with cap and fuse, the fuse being lighted just before dropping the explosive to the ice, and of a length sufficient to permit the cake of ice to float away before the charge detonates. Safety fuse burns at an approximate rate of 2 ft. per minute. Therefore, it should be cut to a length corresponding to time it is desired to fire the charge after lighting.

Another use to which dynamite may be put is in breaking up ice jams at bridge abutments or narrowed river channels, etc. Under such circumstances timely action may prevent considerable damage to construction work. The size of charge is dependent upon the thickness of the ice piled up. In this class of work it is advisable to use a blasting machine and electric blasting caps because of their greater safety. If the ice has piled between piers of a bridge the explosive charges should be placed in the ice midway between piers and all charges fired simultaneously with a blasting machine. Place the charge as near the front of the jam as possible, because there is where the cakes have become locked. If the ice does not break at the first charge successive heavier ones should be used until it starts to move. Where gorges have formed to a considerable thickness making it difficult to dig a hole through the ice with the tools at hand, a small hole can be cut into the ice as far as possible and one or more cartridges exploded to cut the hole deeper. This operation can be continued until a hole is cut either through the ice or to the desired depth.

To prevent the formation of a gorge where it is liable to appear every year at the same point, begin at a short distance downstream and honeycomb the ice all the way

From Job and Office

Hints that Cut Cost and Time

upstream by successive charges. When the thaw comes the broken ice will go out in a body with less likelihood of jamming.

Explosives have also been used on occasions to cut through deep snow drifts and to start snow slides on hillsides.

The proper explosive to use for ice blasting when the charge is placed beneath the ice is a low-freezing, strong, fairly quick acting explosive not readily affected by water. Low-freezing extra dynamite and low-freezing gelatin dynamite are well adapted for the purpose. If the charge is placed on top of an ice floe, a quick-acting explosive should be used, either low-freezing straight nitroglycerin dynamite or non-freezing dynamite of 50 per cent strength or sometimes stronger. Unless a non-freezing explosive is used, particular care should be exercised to see that the dynamite is not frozen. A low-freezing dynamite will not freeze during the short time that it is in the water, but if it is previously frozen it must be thawed before being used.

The materials for ice blasting can most conveniently be carried over the ice in a box fastened to a sled. Full instructions for priming a charge, either by the cap and fuse method or by the electric blasting cap method, may be obtained from literature published by any explosive manufacturer.

Contractor's Sign at Large Building

ON EXTENSIVE construction works, especially on building erection, it is becoming general practice to display large signboards bearing the names of contractors and sub-contractors. In this way adequate publicity is given, while the unsightly appearance of numerous individual signs of various sizes and styles is avoided. A combination sign of this kind, erected by the Wells Brothers Construction Co. at the new Fur-

Sign on Chicago structure during erection lists architects and contractors

From Job and Office

For Contractor and Engineer

niture Mart Building, Chicago, is shown in the accompanying view. It is about 8x30 ft., built up of sheet-metal panels. As a rule, these signs are made and placed by the contractor, but in the case of the Furniture Mart a sign company made an offer to the contractor to erect a satisfactory electrically-lighted sign and as the price was considered favorable this offer was accepted.

In arranging for this sign, the contractors knew that not all of the sub-contractors wished to have their names posted, but on the basis of the expected number the cost was divided between architect, contractors and sub-contractors on a pro-rata basis according to the space used. One form letter was addressed to all sub-contractors telling about the proposed sign and asking them to forward copy if they desired to participate. No further solicitation was used. It is believed that this plan accomplished the desired end satisfactorily, with less trouble to the contractors and no greater expense to any of the participants than if the sign had been made in the usual way. Any method which requires or compels sub-contractors to take space is evidently undesirable. The cost of a large sign is no small item and logically it should be paid for by those who desire to benefit from it.

Construction of a 9-ft. Pipe Line Six Miles Long

THE OAK GROVE hydro-electric project of the Portland Railway Light & Power Co., now under construction on the Clackamas River in Oregon, has a 9-ft. pipe line six miles long. This line will supply the first of three 35,000-hp. generating units which will operate under an effective head of 860 ft., the static head being 925 ft. When the other units are added a second pipe line 11.5 ft. in diameter will be laid paralleling the one now being built. Work on the project is advancing rapidly and the pipe line is expected to be completed by February, 1924, about two months before the plant is scheduled to go into service. A note on the general features of this development appeared in *Engineering News-Record*, Aug. 2, 1923, p. 197.

The distance between intake gates and turbine is 36,334 ft. traversed as follows: 32,900 ft. of 9-ft. steel pipe, which is kept below a controlling hydraulic grade of 2 ft. per 1,000; 2,150 ft. of concrete-lined tunnel, and 1,300 ft. of penstock down a steep incline, the pipe diameter here varying from 8 ft. at the top to 6 ft. at the bottom.

The steel plate for the pipe, varying from 3/8 to 1/2 in. in thickness, was produced at Sparrow Point, Md. and delivered by water to Portland where it was formed into pipe sections 40 ft. long. These sections, weighing about 9 tons each, are transported on flat cars to unloading stations established on the construction railroad at convenient points along the pipe-line grade. Most of these unloading stations are at higher level than the pipe grade and sections are snubbed to the grade on skids with the aid of a cable. On all plate thicknesses of 1/2 in. or less the pipe is reinforced by outside stiffener rings made of 5x3x3-in. angles spaced 2 ft. 9 in.

apart. These angles have been of material assistance in making the pipe rigid for handling.

Laying the Pipe—In the construction program as planned at first, overhead cableways were to be used for moving the sections along the grade from unloading station to final destination. This plan was abandoned in favor of a gantry traveler that would straddle the pipe line and move sections along the grade as required.

The device built for this purpose and shown in the accompanying picture is a structural steel frame mounted on wheels set for track of 11 ft. 8-in. gage. It has a wheel base of 16 ft. and is 12 ft. 8 in. high. The operator's station is on the "upper deck" where the motor, cable drums, etc. are located. Power is supplied by a 50-hp. gasoline motor taken from a 5-ton truck and this is geared down so that a maximum speed of about 250 ft. per minute is made along the track.

When a pipe section arrives on the grade it is rolled between the gantry rails; the gantry moves over it and the section is picked up by cable slings from drums

GANTRY CRANE PICKING UP 40-FT. SECTION OF PIPE

directly overhead. To facilitate rapid handling of the pipe without danger of damage, pieces of old automobile tire casings are fastened to the wood stops over the pipe-way in the traveler to serve as cushions. On delivery the gantry does no exact setting in place, but leaves the section in its approximate position on the grade.

The riveting gang uses a traveler similar to the one already described except that power is supplied by a 7x10-in. steam donkey mounted on top of the steel frame. With this traveler the pipe section is lifted by slings from a boom that can adjust the position of the section as may be required.

With this plan of operation, as many as 16 pipe sections have been placed in 8 hours. The traveler crew consists of five men in addition to which are the crew that snubs sections down from the railroad and the gang that picks up and re-lays track. Track is moved ahead by the gantry and is set by use of the two booms shown in the picture. The rails, in 20-ft. pieces, are spiked to 8x16-in. timbers of the same length, no cross-ties being used.

The pipe distribution is being done by the Hurley-Mason Co., of Portland, who are the general contractors on the project. The J. G. White Engineering Corp., New York, are the consulting engineers. H. A. Rands is construction engineer for the Portland Railway Light & Power Co.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Should Concrete Swimming Pools Be Emptied in Winter?

Sir—In replying to the question, "Should Concrete Swimming Pools Be Emptied in Winter?" asked by Adams & Ruxton Construction Co., in *Engineering News-Record*, Nov. 22, p. 858, the editor advised that, so far as his experience went, such pools were always emptied. While the usual custom is to empty concrete pools, we do not believe it is necessary to do so, and in fact we know of three such pools, located in cold climates, that are not emptied and no trouble has resulted.

If concrete pools are allowed to stand empty and without protection throughout the winter, we suppose that it is done to protect the walls from the horizontal pressures which a sheet of ice on the surface is presumed to exert. We say "presumed to exert" as there seems to be little or no conclusive evidence or positive knowledge as to whether such pressures actually develop in comparatively large bodies of still water contained in rigid walls, and if so, how much pressure actually develops.

As suggested by Adams and Ruxton, we are inclined to believe that a penetration of frost through an unprotected concrete floor slab into a more or less saturated subgrade to a depth of 4 ft. or more would be likely to cause some displacement of the slab with a possible injury to it.

The vertical walls of a pool are designed to resist the normal pressures of the soil when the pool is empty, but they are not designed to resist pressures of frozen earth as the knowledge of such pressures is inadequate for accurate design. A discussion of the formation of ice may shed some light on this interesting problem.

When freezing weather comes, ice forms first around the edges of the pool and as the sheet of ice builds out toward the middle, the thickness at the edge increases. Finally a closure is formed at the middle of the pool and the sheet of ice increases in thickness by building downward. Each additional inch of ice formed on the bottom of the ice sheet displaces approximately 0.1 in. of water. The displaced water finds relief through the path of least resistance which in this case is upward through the sheet of ice, causing it to bulge up slightly at the middle. Thus, if ice were formed with a uniform thickness of 10 in., it would be bulged up into a slight dome shape by approximately 1 in. of displaced water over the surface of the pool. The maximum horizontal pressures against the sides of the pool will be limited by the strength of the slab of ice in resisting the uniform load imposed by the upward pressure of the water. Now if the pool has a minimum width of 25 ft. and the ice a thickness of 12 in. the sheet of ice may be considered as an unreinforced flat slab 12 in. thick with a 25-ft. span uniformly loaded by the upward pressure of the water. If we assume that ice has a tensile strength of 150 lb. per square inch, a slab 12 in. thick having a span of 25 ft. would resist pressure of only 46 lb. per square foot. The increased pressure against the sides of the pool would be approximately equal to that of an additional 9-in. depth of water.

In view of the above considerations, we believe that there is less probability of injury to a well designed pool having minimum dimensions of 20 ft. or more where it is left filled with water to a depth of 1 ft. below the normal level than where it is completely drained for the winter.

A pool at Garden City, Kan., 218 x 345 ft. in plan, with three sloping walls and one vertical, has been allowed to freeze with no apparent damage. A rectangular pool at Abilene, Kan., 60 x 120 ft., with four vertical walls, has

been allowed to freeze every winter since 1914 without damage. Some winters the ice was more than 18 in. thick on this pool. A 63 x 155-ft. rectangular pool with all walls vertical, at York, Neb., has been allowed to freeze several times without injury.

Experience and observations of other engineers and managers of pools would add to the knowledge on this subject. Most assuredly, if it is possible to utilize concrete swimming pools as winter skating rinks, such use should be made of them, thereby adding several months per year to the period of their utility.

Chicago, Ill.,
Dec. 4, 1923.

C. D. HALE,
Civil Engineer.

Shoddy Building Work Briefly Reviewed

Sir—I have just read in the morning's paper of the dismissal of three of the four indictments which grew out of the collapse of the American Theater building in Brooklyn on Nov. 29, 1921, and am prompted to suggest that this item of news affords an opportune occasion for your paper to review the conditions which preceded and surrounded this conspicuous illustration of the ineffectiveness of existing methods of controlling building operations, in the interest of elementary public safety right here in Greater New York.

The following quotations from statements published in the *Brooklyn Eagle*, reporting actual court testimony, ought to prove illuminating in this connection and help to keep alive an interest in all efforts made to improve the underlying conditions responsible for this disaster.

The architect is quoted as testifying that he had employed a relative of the Superintendent of Buildings "to draw up the plans for the steelwork and facilitate the passing of the plans by the Building Department." He is also quoted as testifying that these first steel plans were not used in construction, but that plans made by the steel contractor were later substituted. The architect's connection with the work, however, apparently ended with the furnishing of plans.

The plan examiner in the Department of Buildings is quoted as testifying that he had made 21 objections to the plans submitted by the steel contractor, and that the changed plans were not finally approved until Nov. 2, 1921, a date about two weeks later than the date sworn to by the steel erector as that on which he completed his work. In other words, the steelwork had been erected about two weeks at the time the steel plans were approved.

The steel erector is quoted as saying that he had no working plans, but erected the work "just by putting things where they seemed to fit," and after being shown the approved plans said they were not followed in the work.

The same erector is reported as testifying that he knew the main column was not plumb, that the base plate was too small and that he had forced wedges under it "to take up the slack," and, further, that an excavation was made alongside the column footing and where jacks were used to force the column into an upright position.

The Superintendent of Buildings is reported to have said, "No permit had been issued and I did not know that the building was in course of construction until I received news of the collapse."

The iron inspector of the Department of Buildings is quoted as saying, "I don't think there is an exception in the whole borough where the theater has not been allowed to go ahead before the steelwork has been approved."

Much more of the same sort could be quoted, but the whole situation is well summed up in the memorandum filed by the presiding judge as follows: "There was no architect in charge of the work. There was no competent supervisor. There was no responsible engineer. There was no approved plan for the steelwork. There was no official permit allowing its erection." In spite of all this it has proved impossible to fix responsibility for the loss of life, and the incident will probably be forgotten until the next similar disaster recalls it to attention.

New York, Dec. 7, 1923.

J. B. FRENCH,
Consulting Engineer.

Bending Action in Bascule Bridge Counterweight Failures

Sir—Your article of Nov. 29, p. 872, on two accidents to bascule bridge counterweights attributes these failures to the excessive distortion developed in the members of the steel frame of the walking-beam. The distortional or so-called secondary stresses in the members of this frame are undoubtedly very high, but it seems equally probable that the cause of these failures may be due to the design of the truss members embedded in the concrete counterweight.

This trussing is relied on to pick up all the weight of the concrete by its adhesion to the steel which is embedded in the concrete. The members of this trussing are only designed to take direct stress, and therefore all the adhesion must take place at the panel points or in a plane parallel with the members, if bending in them is to be avoided. The former is of course impossible without developing infinitely high adhesive or bearing unit stresses, and it seems very doubtful if the latter condition can be fulfilled for all the positions of the counterweight. The stiffening effect of the concrete on the embedded members, to enable them to take cross-bending, cannot be effective if the steel is not capable of taking shear in itself, which is the condition here.

Should excessive bending be developed in the embedded members of the counterweight trusses adjacent to their connection to the walking-beam frame, they in turn must exert a moment in the connection, which would produce a tearing action on the chords of the walking-beam and cause them to break at the same point where they would be most severely strained by distortional strains of the walking-beam trussing itself.

Another point to consider is the excessively high range of unit stress in the embedded trussing. It seems questionable whether concrete can permanently adhere to steel that has a frequent strain range of 20,000 to 30,000 lb. per square inch.

The nature of the break at the Lachine bridge would seem to indicate a progressive failure of the bond between the concrete and steel near the point where the trusses deliver their loads to the walking-beam frame. The bond between the concrete and steel being a maximum at the outer edge may have broken down and the fracture continued to spread every time the bridge was operated and the stresses reversed, until this part of the steel frame which had lost the stiffening effect of the concrete was overstressed and failed. The adjoining views show the break in the embedded truss connection which first gave way. It will be seen that the break occurred at the point in the member where it is weakest to resist local cross-bending.

Taking off the side plates on the two bridges should not have weakened the structure, as the bolts passing through

FIG. 1—LACHINE CANAL BASCULE SEEN FROM BACK OF COUNTERWEIGHT AFTER FAILURE

Rear edge of counterweight lies on ground, front end is at top. Right hand side was place of initial failure.

these plates and the concrete were not designed or constructed to take any shear, and the value of any adhesion between these plates and the concrete could not be relied on. It was generally thought at the time of the first accident that, if the plates did partly support the counterweight, the eccentric position of the plates was a real danger to the structures and may have contributed to the cause of the break in the chord.

The correct analyzing of the stresses in the counterweight trussing is a most confusing and complicated problem, and until it is clearly understood the causes responsible for these failures cannot be decided.

Construction Methods in India

Sir—In the East labor is plentiful and said to be cheap. It would appear to be so, if we may judge from the methods adopted in the construction of the "Gateway of India" now being erected on the Apollo Bunder, Bombay. If such a building were being erected in the West, a large crane would have been placed in a suitable position, and worked by some kind of power. But in India, no! Man-power is cheaper, and the contractors follow the primitive method of elevating material by means of pulleys and ropes.

About twenty men hold the rope, and pull up the stone

BUILDING THE "GATEWAY OF INDIA"

a short distance, chanting a kind of sing-song all the time. There are several men stationed on the bamboo scaffolding to direct the course of the stone as it steadily rises to the top of the building. It seems curious that modern methods of hauling should not more quickly be adopted in India.

Hassan, India,

"AJAX."

Providing for Secondary Stresses

Sir—Your editorial of Nov. 29, p. 872, in regard to the danger of failure from secondary stresses, seems to me to be very timely and likely to be very useful. American structural practice in the last 25 years has developed more and more the use of large riveted joints instead of the pin joints used in earlier designs. Probably this tendency has been due partly to the pneumatic hammer, which drives a good field rivet so cheaply. Partly also it has been due to the great increase in stiffness secured by using rivets instead of pins for joint connectors.

We have all known that in some way the structure pays for that increase of stiffness. But there are two considerations which offset a loss of ultimate strength due to secondary stresses in a bridge truss: (1) Impact or vibration is reduced by the increased stiffness, and girder action reduces the stresses from truss action. The total direct stress on the members is thus relieved. (2) The induced secondary stresses before causing failure tend to relieve themselves by permanent bends in the members. The second consideration taken at its face value would seem to indicate that no member could pass the elastic limit from direct and secondary stress alone.

There is a third consideration however, that should make us fearful of the repetitive effect of strong secondary stresses on compression members. Suppose that under a severe loading the given member has such bending from secondary stress that some fibers pass the elastic limit. The member will then take a permanent bend. Under the next application of the same loading the stress from secondary action will not be so large as before, but there will be an increase of eccentricity in the member which might cause the stress in the same extreme fibers again to pass the elastic limit, and cause a further bending. Relief of secondary stress by the bending of heavy tension members might overcome the effect of additional eccentricity in the compression members, but we should not cheat ourselves

into security by maintaining that secondary stresses can never cause failure.

It seems very clear that the exact computation of secondary stresses in minor structures cannot be undertaken or recommended. We have progressed to the point of regarding them in large structures, and even of attempting to remove by initial bending those caused by dead-load. We might, by introducing initial eccentricities in the large compression members, perhaps halve the secondaries from dead-load. In minor frames, if the designer understands secondary stresses and keeps them in mind in laying out his structure and in designing its members, he can keep their effects to a minimum without going through long and tedious calculation. He should make the compression members as shallow in the plane of the truss as other design considerations will permit. He should make gusset plates as small as possible.

Many of us cannot help feeling that a wide gusset plate strengthens a structure. Even in mill-building trusses where a stout kneebrace must take nearly all the wind stress, a big gusset plate riveted into the column makes the structure look more secure. There is no reason, however, why the coming generation of structural engineers should not have the advantage of a clear mental picture of secondary stress action and an understanding of the factors which influence it.

"Modern Framed Structures," Vol. II, contains considerable data from computation of secondaries. Maney's short cut of the slope-deflection method is the most rapid method I have seen in print, but that is not generally available for class-room use. Nevertheless the instructor in structural engineering could send his men out fairly well prepared to analyze secondary stresses or to minimize them in design, if it were not for the chorus of successful graduates of the middle ages, who tell the young engineer, "we never compute them." In late years, this has been somewhat overcome by the publicity given the secondary stress computations on several large bridges, and the interest that the design offices of large bridge companies are showing in the subject.

Your editorial and more discussions in the future will do much to help the instructor who is trying to make a class look upon secondary stress calculations not as advanced drill in calculus trigonometry and algebra but as a fundamental for men who are going to make structural design their life work.

Chicago, Dec. 13, 1923.

ALBERT SMITH,
Consulting Engineer.

Public Service Discouraged

Sir—I have been reading with a great deal of pleasure the articles that you have been presenting from time to time relative to the irrigation problems of the West, and more particularly with reference to the present "business attitude" of the Secretary of the Interior in his dealings with the Reclamation Service. As I have devoted much time in the past to the passage of the original Reclamation Act, and served thereunder for a term of years, and live in arid America, I am, of course, keenly interested in the present situation.

To my mind, the most serious aspect of this Reclamation situation lies in the fact that if high-grade men like Arthur P. Davis and F. I. Newell can be utilized for the creation of a great, meritorious organization, which subsequently is seized by politicians to be operated as a part of a machine for party benefit, then it is basically discouraging to attempt similar organization efforts with such institutions as federal roads, swamp reclamation, harbor improvements, forestry and the like. This discouragement not only applies to competent young men entering the public service, but to such work as we are endeavoring to do through our great commercial organizations. For instance, the Los Angeles Chamber of Commerce has very active committees that are endeavoring to build up legitimate public sentiment in favor of such projects as the Colorado River development, and when they are confronted with a situation such as has been developed, they naturally are discouraged in their efforts.

For these and other reasons, I think that you are fully

justified in using the great influence of your paper in persistently and vigorously condemning any such action on the part of public authorities.

J. B. LIPPINCOTT,

Consulting Hydraulic Engineer.

Los Angeles, Calif., Dec. 5, 1923.

Ethics and Success

Sir—Your editorial, "An Experiment Worth Trying," of some weeks ago prompts certain reflections.

Probably the yet-to-be-unearthed Tel-el-Amarna clay tablets, or the picture writings of prehistoric races, will on deciphering be found to contain well-meant advice to the aged engineer and architect, on how to get a job honorably, and the high ethical standards that ought to prevail in securing it.

The doctor, the lawyer, the dentist, all would starve to death if they lived according to the old theory of occupying a chair in their office and patiently waiting for customers. The practising engineer is in the same category: he must *get* the business.

Assuming "fitness" and "character," he must *make* friends, not alone those of family and boyhood, for rarely can they be counted upon; but the friends made through personal worth and their willingness to introduce, where introduction is of value, and in some cases even personally provide the start.

Competition is the keynote of the day, and that is inevitable throughout every year of the engineer's life, but there can be proper competition and *indecent* competition, and engineers have themselves most to blame for the latter.

A municipal board awakens to the need for an improved water plant, sewage works, refuse disposal system, modern pavements, etc. A local engineer may be quite worthy and even competent, but at the last election he worked for Councilman Jones, so as said Jones is in the minority, Mr. Engineer is out of it. Informal word goes out through the press and the board is swamped with letters from 1,000-mile range, "Me"—"Our Firm"—"My Esteemed Friend"—"We will be glad to advise you briefly without charge"—"Our experience is superlatively beyond that of all our confreres"—etc., ad nauseum.

What happens? The board is drowning; some active member says, call for engineering proposals; and that there may be a semblance of fairness, they do so upon a "Specification of Needs." And what a specification!

Then the deluge; every good-for-naught engineer (and unfortunately a few good) files his proposal and supporting data, and begins his drive to secure votes in the board. The board, usually an unremunerated body, has neither knowledge nor time for real investigation of merits, and with the fear of voters at the next election, if attention is given to other than the lower bidders, either throws up the job, or selects chiefly on the basis of insistent nerve and cheapness, thereby failing often to secure the competent man, and in the long run, putting the community to much greater gross expense.

This is no fancy picture, but a common occurrence.

The writer offers no cure, though absolutely out of sympathy with the method, which possesses no redeeming feature.

If engineering is to be considered a profession, and if the engineer is to be looked upon as one worthy to give, and charge for, advice, such practices must end.

The card in technical journals, papers before professional societies, experiments made and written up, attendance at and participation in engineering meetings, all help, but do not bring much bread and butter.

Membership and active service in civic organizations, appearances before municipal bodies, for other than self-exploitation, are excellent.

Letters of introduction to parties having work in charge, or responsibility for it, are perhaps the most powerful aids to landing the job, while in absence of such possibility a frank request for interview, or dignified offer of services and simple statement of qualification, with a few names for reference, may sometimes bring a reply and once-in-a-while land a job.

One piece of work well done usually leads to others. In closing, at the risk of the senile charge, let the writer say, while much unfortunate fact exists as to contrary practice: "Ye cannot serve two Masters."

New York City,
Dec. 20, 1923.

LOUIS L. TRIBUS,
Tribus & Massa, Engineers.

Quantity Progress Profiles

Sir—The disadvantages of showing monthly progress of railroad or canal construction in colors or hatching on the standard profile platted on either plates "A" or "B" are well known. The distorted relation between elevation and volume, necessity of showing "finishing" as well as bulk movement of material, different methods of construction under different conditions, irregularity in application of force in different months, and the different free-hand styles or personal equations of the various resident engineers who compile the progress are the most conspicuous of these.

QUANTITY PROGRESS PLATTED SEPARATELY

Some fifteen years ago when the writer was in Idaho he was shown a progress profile in use on irrigation construction, of which the enclosed is a rough sample, made from memory. The system used was different hatching for each month's progress on the upper or quantity profile, made on transparent paper. Prints were taken from this, as required.

It seems that the quantity profile will give a more accurate view of progress than to hatch or color the lower profile; that the method is feasible for use on canal construction, and on plate "B" is adapted to railroad construction on light grades and not to irregular ground, but for mountain work would be impractical or would require the full width paper instead of the usual half width.

It is also evident that the quantity profile could not be platted until after the quantities had been computed and that probably considerable extra work and expense are involved.

In some twenty years of construction experience, the writer has never seen a satisfactory progress profile using the standard plating, and would like to learn from actual users their ideas on the "quantity profile" and whether the benefits from this same have warranted the additional trouble before putting it to actual use.

San Francisco, Calif., H. S. MARTIN,

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

The Municipal Docks and Terminals of Jacksonville, Fla. will earn a net profit of \$80,000 this year according to an estimate made by the general manager.

The Annual Convention of the County Commissioners of Ohio will be held at the New Southern Hotel, Columbus, Feb. 5 and 6. This meeting will be followed by the convention of the Ohio Engineering Society, which will be held at the same hotel Feb. 7 and 8.

Col. Frederick Stuart Greene, New York State Superintendent of Public Works, it is understood will advocate in his recommendations to the legislature a tax on the sale of gasoline, which it is estimated would provide a fund of \$20,000,000 yearly which could be used for maintenance of state and county highways, and render unnecessary legislative appropriations.

Report From the Contractor's construction camps at the Moffat Tunnel in Colorado stated that on Dec. 4 a total of more than 1,000 ft. had been driven in the two headings. The pioneer heading at the west portal had been advanced 654 ft. and the pioneer heading on the east end 400 ft. At the west end the bore is now in hard rock and since passing the point where timbering was necessary much more rapid progress had been made.

A Resolution Adopted by the Senate provides for extending the scope of the special deeper waterway committee of the Senate so as to provide for House participation in its membership. The resolution authorizes such a joint committee to continue the work already done by the Senate committee in investigating the problem of the 9-ft. channel from the Great Lakes to the Gulf of Mexico. Included in the proposition is the matter of the navigability of the Ohio and the Missouri rivers.

The Presidential Nomination of George K. Burgess to be director of the Bureau of Standards was confirmed by the Senate on Dec. 18. The Senate also confirmed the nomination of C. L. H. Ruggles to be assistant to the Chief of Ordnance with the rank of brigadier-general and of John W. Joyce to be assistant to the Chief of Ordnance with the rank of brigadier-general, and of Samuel McRoberts and John R. Delafield to be brigadier-generals in the Officers Reserve Corps.

The Spavinaw Water Project under construction to furnish water from the Ozark Mts. to Tulsa, Okla., is 70 per cent complete. The gravity concrete dam of 55 ft. maximum height on the Spavinaw Creek is nearly finished, the 10,000-ft. 84-in. tunnel will be completed by Feb. 15, 1924, and the 53 miles of 54- and 60-in. reinforced-concrete pipe line and pumping station at the end of pipeline should be completed in May, according to W. R. Holway, engineer in charge of the construction.

Accident on London Tube Subway Stops Traffic

In enlarging the diameter of the City & South London R.R., one of the first of the "tube" subways of London, England, an old storage well or cistern was pierced, causing an inrush of sand and water. This flow of material caused a great cavity to form, so that water and gas mains and electric conduits were broken. The gas finally exploded and blew up a section of the street, Newington Causeway, about 30 x 20 ft., but no harm was done before the broken main was shut off. The 18-in. tunnel enlargement was being carried on while traffic was maintained in the original tube, but after the accident all traffic stopped, arrangements being made to handle the passengers on adjacent bus lines.

Traffic was also interrupted temporarily on the Southern Ry., which crosses the street at this point, in order that the bridge foundations might be inspected, but it was found these had not been disturbed by the slide or the explosion.

Philadelphia Sesqui-Centennial Plans Suspended

Work for the sesqui-centennial exhibition in Philadelphia has been definitely suspended until after Jan. 1, 1924, when the new city administration in Philadelphia goes into office. Col. John Price Jackson has resigned as executive director of the Exhibition Association, and the salaried personnel has been reduced to three persons. Suspension of all work came during the unsatisfactory campaign to raise \$5,000,000 by popular subscription, in addition to the \$1,000,000 previously subscribed. It was precipitated by Mayor Moore's opposition to the plans of the Association. The mayor declared that the Association's plans (*Engineering News-Record* of Sept. 6, 1923, p. 403) though modified from the original proposals for an exhibition, were still too elaborate and extensive. Mayor-elect Kendrick has intimated that he is favorable to the sesqui-centennial exposition.

Agreement Makes New Construction Possible at New Orleans

By an agreement with the City of New Orleans the Louisville & Nashville R.R., has ceded to the Dock Board property along the levee at St. Joseph St., which has been the subject of dispute as to title for a number of years. In return, the railroad company receives assurance of undisputed rights to the land which it occupies back of St. Louis St., upon which it will now erect a storage warehouse at an estimated cost of \$750,000.

The New Orleans Dock Board will erect a wharf and shed along the levee property which it has acquired, and which is expected to cost about \$1,000,000.

New Hudson River Bridge Project For New York City

Plans for a highway bridge across the Hudson River in the upper part of New York City have been submitted to the Port of New York Authority by Governor Silzer, of New Jersey. The project was developed by O. H. Ammann, formerly deputy chief engineer of the New York Connecting R.R. It provides a single-span suspension bridge at Fort Washington Point, on a line lying between 178th and 179th Sts., New York, reaching the New Jersey bank at Fort Lee. The main span is 3,400 ft. long and the side spans each 700 ft. Double eyebar chains are the carrying members. They are spaced 90 ft. apart and provide for a roadway width of 80 ft. on the main deck, with footwalks outside. This main deck is assigned to highway use, and accommodates eight lines of vehicles. Four electric-railway tracks are placed on four narrow cantilever lower decks formed by bracketing out to either side of the posts in both stiffening-truss planes. The truss depth is unusually small, being only 35 ft.; the top chord is at the level of the main deck and the bottom chord at the level of the lower edge of the trolley brackets.

Mr. Ammann estimates the cost of the structure at \$30,000,000 and its time of construction at four years. He claims that it will give quicker relief to cross-river traffic than any other crossing proposed. In conjunction with the existing Washington Bridge across the Harlem River it will provide a direct connection between New Jersey and the Westchester and New England regions without carrying the traffic through the congested midtown section of New York. Tolls are estimated to be sufficient to pay fixed and operating charges even in the first year after completion.

Kansas Engineering Society Holds Convention at Wichita

Outstanding features of the annual convention of the Kansas Engineering Society held in Wichita, Dec. 11-13, were an address by P. L. Brockway, city engineer of Wichita and president of the association, and a talk on aerial photography by Major L. B. Roberts. Mr. Brockway urged greater participation in civic affairs by engineers, asserting that engineering was closer related to business than any of the professions. Major Roberts explained in detail the use of aerial photography in reconstructing existing maps. Another interesting speaker was Clark Jacoby whose discussion of flood protection was directed mainly to rivers near Wichita.

The first day of the convention was devoted to various officers' and committee reports. Committee reports occupied most of the morning and afternoon sessions of Dec. 12. A highway symposium was the principal feature of the third day's session.

Dr. Elwood Mead Returns From Extended Trip Abroad

Returning from a nine-months trip to Australia and the Holy Land where he served as reclamation consultant for the British Government, Dr. Elwood Mead of Berkeley, California, noted irrigation engineer, began to serve Dec. 20 as a member of the special advisory committee appointed by Secretary of the Interior Work to study government reclamation.

Dr. Mead arrived in New York Dec. 19 from Jerusalem and went to Washington the next day, calling upon Secretary of the Interior Work before joining the committee. Dr. Mead was employed by the Australian Government for many years to organize the settlement activities on its irrigated lands and during his recent trip served on a British Commission to investigate the difficulties that have developed in connection with Australian reclamation. He also spent a month in Palestine where at the request of the Zionists he traveled over the country with a view of passing on the advisability of reclamation projects in the Holy Land.

Dr. Mead left Dec. 20 for Berkeley where he is a professor of rural institutions of the University of California and will join the special advisors when its members begin next month a tour of a number of reclamation projects in the West. Following this visit of the committee he will return with them to Washington and assist in the preparation of the final report of the committee that will be made to the Secretary of the Interior to be later submitted to the President and to Congress.

Minnesota Metropolitan Planning Commission Scheme

Progress on the formation of a Metropolitan Planning Commission for Minneapolis, St. Paul, and vicinity was made at a second meeting devoted to the subject held on Dec. 13 under the leadership of the Northwestern Section of the Am. Soc. C. E. With G. H. Herrold as acting chairman, the meeting on Dec. 13 arranged for two committees, one on organization and one on a tentative boundary line for the district, the latter consisting of E. H. Hewitt, Minnesota Chapter, A.I.A., A. M. Best, assistant to the vice-president, N. P. Ry., representing the Northwestern section, Am. Soc. C. E., and James T. Elwell, president, Minneapolis City Planning Commission. The plan is to have Metropolitan Planning Commission self-organized, but with a view to getting legislative legalization of the commission and its work.

Milwaukee Zoning Ordinance Upheld by State Court

The constitutionality of the zoning ordinance of Milwaukee, Wis., was upheld by the State Supreme Court on Dec. 11. The decision upholds zoning as an exercise of the police power and denies that it results in taking private property for public use in such a way that compensation should be paid. The plaintiff sought to compel the building inspector of Milwaukee to grant a permit for a dairy building in a residence district from which business is excluded by the zoning ordinance. The opinion in part, was as follows:

"If, in the prosecution of governmental functions, it becomes necessary to take private property, compensation must be made, but incidental damages to property resulting from governmental activities or laws passed in the promotion of the public welfare is not considered a taking of the property for which compensation must be made.

"This is no new idea, although it has but recently taken the form of legislation. Everyone who has observed the haphazard development of cities, the deterioration in the desirability of certain residential sections by the encroachment of business and industrial establishments upon and into such sections, resulting in the consequent destruction of property values and in the ultimate abandonment of such sections for residential purposes has appreciated the desirability of regulating the growth and development of our urban communities.

"Fresh air and sunshine add to the happiness of the home and have the direct effect upon the well being of the occupants. It cannot be denied that a city systematically developed offers greater attractiveness to the house seeker than a city developed in a haphazard way. The one compares to the other as a well ordered department store compares to a junk shop."

Highway Traffic Officer

This is one of the Pennsylvania State Highway Department's motorcycle patrolmen. The innovation of detailing a special highway police force under the highway and not the police department, has but recently been established.

Convict Road Force of 102 Men Moved to New Job

The California Highway Commission on Dec. 5 and 6 moved 102 prisoners several hundred miles from a road camp on the Klamath river in Siskiyou county to Briceburg on Merced river where the convicts will begin a two-year job in building the state highway through the rugged Merced river region into Yosemite National Park.

The men and their equipment were moved from their Klamath river camp in trucks to the railroad station where two day coaches and two baggage coaches were waiting on a siding. Baggage, camp equipment and commissary were loaded into these cars which were then attached to a regular Southern Pacific train about noon. At Merced they were transferred to the Yosemite Valley R.R. arriving at their destination on the afternoon of the second day.

To Eliminate Grade Crossings

Following a joint conference between the state highway commissioner, the governor of Alabama, and officials of practically all railroads operating in Alabama, an agreement has been reached where the highway department will inaugurate a grade-crossing elimination program, in which the state will pay 50 per cent and the railroad 50 per cent of the cost. The agreement requires only the formal approval of the chief executives of the railroads before it can be put into effect.

Army Engineers Report Adversely on Tombigbee Deepening

Washington Correspondence

An adverse report has been made by army engineers on the project to deepen the Tombigbee River in Alabama and Mississippi and connect it by a canal with the Tennessee River. As a result of a preliminary survey made in accordance with the rivers and harbors act of 1922, the engineers have reported to Congress that the project would be costly, that 63 locks would be required, thus making it cumbersome, and that the proposed waterway would practically parallel the Mississippi River without material benefit to commerce.

While the item for the survey was included in the rivers and harbors act on the suggestion that commerce would be benefited by the improvement, one of the other suggestions put forward by advocates of the project was that by connecting the Tombigbee and Tennessee rivers a means of relieving floods in the Mississippi River would be provided as flood waters from the Tennessee could be diverted to the Gulf through the canal. No mention of this subject is made in the engineers' report.

Work Progresses on Camden Terminal of P. & R.

Company Officials Confident New Terminal Will Be Ready for 1924 Seashore Season

Special Correspondence

Rapid progress is being made on the construction of the new Camden, N. J., terminal of the Philadelphia and Reading Ry.'s seashore lines. Work on the laying of tracks, construction of the fill-in, the piling, erection of steelwork, used in connection with the terminal, signal tower and battery house to be butterfly shelters, and building of the has progressed so satisfactorily that officials of the company are confident the terminal will be ready for service by the opening of the seashore season in 1924.

The new terminal will be a thoroughly modern two-story structure of steel frame and brick with stone trimmings, on a concrete foundation built on piles. It will house the electrically-operated ferry slips, the trainshed containing 14 tracks, a concourse 328 ft. long and 105 ft. wide, waiting rooms for men and women, a restaurant, and the offices of the Delaware River Ferry Co. and of the Philadelphia and Reading Ry.'s seashore lines. The office building, on the land side of the terminal, will be a two-story structure 115 ft. long and 42 ft. wide. A brick power house is located at the opposite end of the concourse.

The hydraulic fill of 319,388 cu.yd. under the station proper, and the fill of 30,000 cu.yd. at the Jackson Street end of the terminal are now practically completed. Most of the creosoted wood piling used in the ferry slips is in

Wheeling, W. Va., Accepts Balmer Refuse Incinerator

The 70-ton garbage and refuse incinerator of the Balmer type, the first of the kind in the United States, has been accepted by the city authorities of Wheeling, W. Va. Some weeks before acceptance the plant was tested by H. L. Campbell, city engineer, and G. R. Kress, of Clark & Kress, a local engineering firm. In the report on this test it was stated that during a trial extending through a period of five or six days 14.84 tons were burned in 8 hr. or at the rate of 44.5 tons in 24 hr.—against the guarantee of 70 tons. The report contained no recommendation as to acceptance. Between the time the contract was let and the test made a city election resulted in a change of administration, including the mayor, at least a majority of the city council, and subsequent to the election, the city manager and city engineer. This change was considered locally to be unfavorable to the incinerator but, as stated, the plant has been accepted by the city.

Right to Double Wanauque Water Development Granted

The right to develop the Wanauque water supply storage to its full capacity of some 100 m.g.d., doubling the original amount, has been granted to the North Jersey District Water Supply Commission by the New Jersey Board of Conservation and Development. The commission has built the foundations for a dam at Midvale designed to store water to give 50 m.g.d. and work is well along on a contract for an 8-mi. tunnel to form a part of the conduit from the reservoir to Newark, for which city the Commission is carrying out the work.

Drainage Congress Announces Program for Meeting

Papers listed for the program of the National Drainage Congress, at St. Louis, Jan. 16-17, are numerous and of varied character, as shown by the following partial list: "Drainage of Horicon Marsh," E. R. Jones, University of Wisconsin; "Drainage in Iowa," C. C. Ayers, Iowa State College; "Future Work in Louisiana," A. T. Dusenbury, New Orleans; "Results in North Carolina," Dr. J. H. Pratt; "Drainage Development in Relation to Rainfall and Wild Animal Life," E. V. Willard, Minnesota Commissioner of Drainage; "Adapting the Method of Reclamation to the Land," J. T. Stewart, St. Paul; "Expansion of Farming Area," Dr. L. C. Gray, U. S. Dept. of Agriculture; "Improved Methods of Long Term Financing," H. C. Wallace, Secretary of Agriculture; "Relation of Colonization to Reclamation," F. H. Newell, Washington, D. C.; "Cost and Cost Finding," L. S. Hidingier, Memphis, Tenn.; "What Drainage Has Accomplished," S. H. McCrory, U. S. Dept. of Agriculture; "Crops on Peat and Muck Lands," G. R. S. Elliott, University of Minnesota; "Fluctuation of Ground Water Level," S. A. Norling, Denmark; "Outlet Drainage," E. R. Jones, University of Wisconsin; "Land Reclamation and Game Reserves," C. H. Young, Muscatine, Iowa; "Wing Dams and Levees in the Mississippi Valley," Col. Potter, Mississippi River Commission; "Oil Engines for Dredges and Draglines," Geo. B. Massey, Chicago; "Drainage Legislation," R. B. Oliver; "Progress in the Everglades," F. C. Elliott, chief engineer, Okeechobee Project; "The Policy of the Interior Department in Regard to Western Reclama-

ARTIST'S SKETCH OF PHILADELPHIA & READING \$2,000,000 CAMDEN TERMINAL FOR SEASHORE LINES

place. All of the structural steelwork over the concourse has been erected, and a portion of the steelwork over the headhouses has been erected. All tracks, both those in the train shed and those in the yard adjacent, have been laid, and work has been completed on the intricate switches where the terminal tracks converge. The butterfly shelters over the train platforms are well under way.

The signal tower and battery house, which will be the largest on the Reading system, is about 50 per cent completed. It will be a three-story building of brick and concrete, 53 ft. long and 17 ft. wide. The first floor will be used for the storage of signal equip-

ment and for the heating plant. On the second floor will be the generator and battery racks, the relay racks, and the general working apparatus of the tower. The third floor will be occupied by the lever room containing 75 lever frames which will control all of the traffic in and out of the terminal.

The ferry slips at the foot of Chestnut Street, on the Philadelphia side of the river, have been electrified in anticipation of the opening of the new terminal.

tion," D. W. Davis, Chief of Bureau of Reclamation; "Value of Reclamation to the Railroads," Wm. Sproule, president, Southern Pacific R.R.

Highway Course in Tennessee

A short course in highway engineering for highway engineers is to be held at the University of Tennessee Jan. 7 to Feb. 2. The course is to be given under the joint auspices of the university and the state highway department. The course will include mathematics, computation and drawing, highway surveying, materials testing, a general course in highway engineering, highway economics, transportation, and highway organization.

Demolition Contracts Awarded for Delaware River Bridge

Award of four contracts for demolition work was made by the Delaware River Bridge Joint Commission at its meeting in Philadelphia on Dec. 21. Three of the contracts will be performed at a total cost to the commission of \$17,863, while the fourth contract is on a basis that the contractor will pay the commission the sum of \$2,812, making the net cost of the four contracts, \$15,051. The demolition is to prepare the sites of the approaches for the bridge on the two sides of the river. Bids were received on nine sections, four being on the New Jersey side of the river and five on the Philadelphia. Three of the Philadelphia bids and two of the Camden bids were rejected, and these portions of the work will be readvertised for bids to be received on Jan. 16, 1924.

Sacramento's New Water Filters To Be Started Dec. 31

Sacramento's new 48-m.g.d. water filtration plant is to be put in operation New Year's Eve. President Coolidge will press a button in the White House connected by wire with the control board at the filter plant. A three-day celebration in Sacramento will follow.

Engineering Societies

Calendar

Annual Meetings

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.; Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN TRADEBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 11-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-24, 1924.

ENGINEERING INSTITUTE OF CANADA, Montreal; Annual Meeting, Montreal, Jan. 22, and Ottawa, Jan. 23, 24, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich.; Annual Meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, Chicago, Ill.; Annual Meeting, Chicago, March 13-15, 1924.

AMERICAN WATER WORKS ASSOCIATION, New York City; Annual Convention, New York City, May 19-21, 1924.

The Minnesota Federation of Architectural and Engineering Societies will hold its third annual convention Feb. 1 and 2, 1924 at Duluth.

The Dayton, Ohio, Section of the American Society of Civil Engineers has elected the following officers: J. H. Kimball, president, for one year; and J. K. Grannis, vice-president, for two years. C. D. Putman, vice-president, and C. H. Eiffert, secretary-treasurer, remain in office for another year. At

this meeting, E. W. Lane, who has just returned from three years' work in China, gave an interesting talk on "Flood Problems on the Huai River."

The Engineers' Club of Trenton, N. J., announces the opening of its new headquarters in the Stacy-Trent Hotel, Trenton. H. G. Acock is secretary of the club.

The Engineers Subdivision, Chicago Association of Commerce, Dec. 19, elected the following officers: J. L. McConnell, chairman, and Frank D. Chase, vice-chairman.

The South Dakota Engineers' Society will hold its annual meeting at Huron, So. Dak., Jan. 9 and 10. The annual dinner and some of the sessions will be held jointly with the Associated Contractors of South Dakota. R. E. Bragstad, Aberdeen, So. Dak., is secretary of the engineers' society; H. Rettinghouse, of Sioux Falls, is president.

Personal Notes

RIVERDALE CONSTRUCTION CO. announces change of address from 1440 Broadway, New York City, to 2511 Grand Central Terminal, New York City.

IVAN E. GOODNER, Olympia, Wash., chief engineer of the department of conservation and development in the state of Washington, has resigned to go into private practice in California, and his resignation also covers his connection as chief engineer of the Columbia Basin state survey. Mr. Goodner has served as chief engineer of the Paradise Irrigation District in California, assistant division engineer of the Miami Conservancy District, Dayton, Ohio, and chief engineer of the Columbia Basin irrigation project in Washington.

ALLEN CLARBY has been appointed county road engineer for Christian County, Kentucky, with headquarters at Hopkinsville, Ky. He succeeds J. H. Dillman who had been county engineer for a year.

D. W. COLE, formerly of Marietta, Ga., who was in the U. S. Reclamation Service from 1904 to 1919, is now connected with the engineering department of the Electric Bond & Share Co., New York City. In the U. S. Reclamation Service, Mr. Cole was engineer on the construction of the Shoshone Dam in Wyoming, engineer in charge of the Truckee-Carson irrigation project and construction of the Lahontan Dam in Nevada, and senior engineer and resident manager of the Boise project, at which time he was senior engineer of the Western district of the Reclamation Service. He has also been engaged in various municipal water-works and in power developments.

P. F. AUER, who is now located in Little Rock, Ark., as resident engineer for James Stewart & Co., general contractors, changed to this work from being field engineer for the St. Louis Coke & Chemical Co.

CLAIR A. INSKEEF has changed location from county maintenance engineer

of Logan County, Ohio, to civil engineer on surveys and construction for the Biscayne Engineering Co., and his new address is Miami, Florida.

JAY J. MORROW, Corps of Engineers, has been made a brigadier general in the Engineer Officers' Reserve Corps. General Morrow is governor-general of the Canal Zone. He has served as chairman of the Alaska Railroad Commission, and as chief engineer of the First Army, A. E. F., in France.

QUINCY B. NEWMAN has been appointed chief engineer of the U. S. Coast Guard, and his appointment was confirmed by the Senate on Dec. 19.

LEWIS E. ROBERTS, formerly resident engineer on levee and drainage work with T. N. Jacob of St. Louis, Mo., has gone into private engineering practice in Peru, Ind.

JAMES H. RYAN is now bridge design engineer for the Missouri State Highway Department. He was formerly structural draftsman with the Shoemaker Satterthwait Bridge Co. at Pottstown, Pa.

CHARLES H. OSBORNE, builder and consulting engineer, has been appointed building inspector for Baltimore by Mayor Howard W. Jackson. Mr. Osborne held the same position several years ago. He succeeds J. Frank Crowther.

J. H. BRAY, recently assistant engineer for Red River County, Texas, has been appointed county engineer of Van Zant County, at Canton, Texas.

Obituary

JAMES FINLAY, for many years erecter superintendent of the Dominion Bridge Co., in Canada, died in Vancouver, B. C., Dec. 11. One of Mr. Finlay's most notable achievements was the placing of the two large spans of the Canadian Pacific Ry. bridge over the St. Lawrence River at Lachine, Que., in 1913.

LIEUT.-COL. GEORGE E. GIBSON, engineer, Albany, N. Y., died at his home in that city Dec. 19, aged 43 years. Colonel Gibson served through the war as engineering instructor at Madison Barracks.

JAMES E. HOOD, Mack, Colo., general manager of the Uintah Railway Co., Colorado, died Dec. 16 from an accident received on the line Dec. 13. Mr. Hood was born in Pennsylvania in 1869 and was a graduate of Allegheny College, Pittsburgh. His early service was in the engineering department of the Erie R.R., for which road he was rated division engineer. He entered the service of the Great Northern Ry. and worked on the construction of that line into Spokane and Seattle from Havre, Mont. In 1910 he was appointed superintendent of the Chicago, Milwaukee & St. Paul Ry. During the war he was commissioned a lieutenant, going to Siberia where he was promoted through the various grades to major. He was made general manager of the Uintah Ry. in 1921.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Income Tax Returns Show Size of Various Industries

Corporation returns to the Bureau of Internal Revenue show that 356,397 concerns made tax returns in 1921. Of that number, 171,239 had a net income of \$4,336,047,813. On that amount they paid a total tax of \$701,575,432. There were, however, 185,158 of the corporations reporting that had deficits rather than income. The aggregate of those deficits was \$3,878,219,134. Detailed figures for certain industries related to the engineering field are as follows:

Industry	No. of Corporations	Net Income	Total Tax
Chemicals:			
Paints and varnishes	664	\$7,591,201	\$1,217,053
Quarrying:			
Stone	493	5,955,125	894,934
Clay, sand, gravel	720	5,428,312	920,448
Stone, clay and glass:			
Cut building stone, etc.	1,495	28,304,171	4,724,338
Brick, tile, terra cotta	1,600	20,300,342	3,586,023
Glass and glass products:			
Plate and window	552	20,423,723	3,611,746
Combinations of stone, clay and glass manufacture	34	738,263	109,521
Rail transportation:			
Steam railroads	609	291,113,607	29,650,857
Electric railroads	458	33,843,158	3,847,446
All other railroads	394	30,861,445	3,816,544
Total rail transportation	1,461	355,818,210	37,314,847
Other public utilities:			
Electric light and power companies	1,900	61,207,294	7,754,355
Gas companies	569	22,008,381	3,173,271
Telephone and telegraph companies	1,949	113,040,315	12,912,536
Waterworks	1,459	11,827,922	1,193,438

The gross income of corporations in the various groups is shown by the following:

Industrial Groups	Total No. of Corporations Reporting	Gross Income
Mining and quarrying	17,660	\$3,888,876,370
Transportation and other public utilities	19,105	9,000,656,163
Chemicals	5,924	3,878,880,302
Stone, clay and glass	3,681	953,756,897
Metal and metal products	15,536	9,805,136,797

Lumber Standardization Adopted By Unanimous Action

The national conference on lumber standards, held in Washington, D. C., Dec. 12 and 13, agreed to a generally satisfactory compromise on the vexed questions of the dressed thickness of standard boards and dimension. It was unanimously voted to set up a standard of $\frac{3}{4}$ in. for standard boards, with $\frac{5}{8}$ in. as extra standard; and a standard of 1 $\frac{1}{2}$ in. for dimension and 1 $\frac{3}{4}$ in. for extra standard dimension.

The recommendations of the Central Committee on Lumber Standards provided for a minimum standard. The adoption of the "extra standards" was made to meet the views of the retailers who favored $\frac{3}{4}$ in. as the single standard for boards and 1 $\frac{1}{2}$ in. for dimension. Secretary Hoover characterized the action taken as "the greatest forward movement in the direction of public service ever made by the lumber industry."

The remainder of the Central Committee's recommendations were adopted with minor changes and the commit-

tee was instructed to proceed with the consideration of the question of short and odd lengths, rough-dry sizes, box lumber, mouldings and other subjects and report again next May.

Big Output of Motor Vehicles

Production reports totalling 325,125 cars and trucks made in November, submitted at the directors meeting of the National Automobile Chamber of Commerce Dec. 6, bring the 11 months output to 3,717,709 which indicates that the year's total will reach 4,000,000. This will be a gain of more than 50 per

Lining Up Turbine-Driven Pumps To Kill Vibration

Practical Suggestions Made for Leveling Bed-Plate and Securing Even Bearing of Coupling Faces

GEARED turbine-driven centrifugal pumps now used for supplying cities with water are less heavy than reciprocating pumps, and as they contain no unbalanced reciprocating masses they are also less apt to produce vibration, generally requiring less costly foundations. Because of their high rotational speed, however, great care must be applied to insure correct alignment. The following notes on testing for alignment embody practice recommended by the De Laval Steam Turbine Co., Trenton, N. J.

In handling a large bed-plate for the support of a geared turbine-driven centrifugal pump care should be taken to avoid distortion by shock in handling. Although the bed-plate may have ample depth and rigidity for its purpose when properly supported, cast-

LINING UP UNITS WITH "FEELER" BETWEEN COUPLING FLANGES

iron, like all other metals, is flexible and will distort appreciably under stress. It may even receive a permanent set so that it will be difficult to pull it back into its original alignment. It is therefore advisable to keep the machine on the skids on which it was originally shipped until it is placed on its foundation.

LEVELING THE BED-PLATE

An easy way to level the bed-plate on its foundation is to place small steel plates with taper wedges under the edge of the bed-plate, driving up on the wedges until the proper alignment and level are obtained. These wedges should be placed from 12 to 15 in. apart on small machines, and 24 to 30 in. apart on large machines. The planed surfaces of the bearing brackets may be used as leveling pads after removing the bracket caps. After the leveling has been completed, however, tests should be made for correct alignment by examining the two halves of the flexible coupling to see that their faces are parallel and that the center lines of the shafts coincide. The couplings used in De Laval pumping units, as shown in the accompanying photograph, are accurately finished on the periphery and on the inside surface by means of a grinding machine at the factory so that they run perfectly true and can be depended upon in correct alignment.

CHECKING COUPLING ALIGNMENT

When checking the alignment of a coupling the bolts can be removed so that the two halves are entirely free. First insert a leaf-gage or feeler between the two halves at a number of

cent over 1922, which was in itself a record year.

Register Trade Marks Abroad, Commerce Dept. Urges

It has been one of the regrettable features of American trade abroad, according to the Department of Commerce, that until recently insufficient attention has been given to the means of protecting and reserving to the original owner the value attaching to a brand mark. Under the United States law a right in a trade-mark is obtained simply through continued use, without any further steps on the part of the originator of the trade-mark. In the majority of foreign markets, however, the right is regarded as being vested in the first person who makes public claim to the mark through registration with the local patent office.

Even in those countries where consideration is given to the fact of prior use, and infringements may be contested under common law, the simple and relatively inexpensive process of registration of a trade-mark is a desirable thing, since it creates prima facie evidence of ownership in case of dispute and affords a basis for obtaining damages from infringing concerns. Trade-mark registration is decidedly less expensive than trade-mark litigation, and there should be included, as part of every enlightened export program, an examination of the means for protecting the value of the trade-mark in the new mark is just as soon as the article begins to show promise of appreciable sales in the particular country.

points; the space should be uniform around the circumference or should not vary more than 0.002 in. A steel straight-edge can then be placed across the two coupling halves and should have an even bearing on their surfaces. This checking by means of a straight-edge should be done at not less than four points evenly spaced around the circumference. If the coupling is not in correct alignment, it will not operate satisfactorily at high speeds, and will tend to produce vibration and strain in the bearings and shaft. Excessive wear of coupling pins or bearing is an indication of poor alignment.

When the alignment has been completed the bed-plate should be filled partly or wholly with cement grout in order to maintain alignment and prevent distortion by piping or other strains. Foundation bolts are not necessary, but may be advisable to assist in maintaining alignment. After the grouting has set the alignment should again be checked, as in rare cases the swelling of the cement causes a slight distortion.

In attaching piping to the pump care should be taken to see that the flanges fit properly. If they do not come parallel and do not meet they should not be pulled up with flange bolts, as this may strain the pump casing, bed-plates and piping, and will invariably result in distortion, with possible vibration or breaking of pump casing or piping.

Business Notes

THE LITTLE RED WAGON Co., Omaha, Neb., announces that it has purchased the business of Stroud & Co. and will continue the manufacture of the Stroud line of road-making machinery, including elevating and blade graders, scrapers, dump wagons, plows and road drags.

SMITH ENGINEERING WORKS, Milwaukee, has opened a branch office at 50 Church St., New York in charge of Donald D. Barnes, formerly district manager in Chicago. Mr. Barnes is an engineer with wide experience in design of quarry and gravel plants. The Chicago office will be continued in the Old Colony Building under management of Victor H. Jones, formerly associated with American Blower Co.

C. B. ADAMS and S. P. HOLMES have incorporated under the name C. B. Adams & Co., Chicago, to represent the Union Iron Works of Erie, Pa., manufacturers of steel water-tube and fire-tube boilers; the Erie Engine Works, of Erie, Pa., manufacturer of slide-valve engines; and the Sims Co. of Erie, Pa., manufacturer of water-heating apparatus.

BARBER ASPHALT Co. has installed a new power plant at its works in Maurer, N. J., to supply steam, electricity and compressed air to its three manufacturing units, the roofing plant, oil refinery and asphalt plant. The new building is 115 ft. long with boiler room 75 ft. wide and engine room 41 ft. wide. There are five 520 hp. boilers, and a 300 and a 500 kw. turbine. While the

boilers are stoker equipped all but one unit are fitted for burning fuel oil, one of the company's products. Lockwood, Greene & Co. were engineers for the plant.

SEATTLE MACHINE WORKS announce that experiments on the Johnson airless injection Diesel engine have been completed. The company is now preparing to manufacture these machines for marine service, electric generating sets and contractors' equipment.

Equipment and Materials

New Heavy Duty Hoists

A new heavy-duty hoist, adaptable to cableways, tail rope systems and general haulage, has been added to the line of the Treadwell Engineering Co., Easton, Pa. The equipment is operated by electric motor and special attention has been given to the elimination of cast iron in the brake mechanism.

The frame is a gray-iron box type casting with motor and intermediate shaft bearings mounted on it, thus insuring perfect alignment. Bearings are of cast iron, of the pedestal type, and bearing caps are machined at the joints. All bolts are provided with lock-nuts. To insure absolute rigidity the bearings and pedestals are provided with machined tongues which fit into grooves in the frame. Gears are either of semi-steel or cast steel, with cut teeth.

The friction clutches are of the single-face cone type operated by a screw thrust. The drum consists of two heads or flanges bolted to and supporting a cylindrical shell of cast iron. Each drum is provided with one or two brakes, as ordered, of the differential type. For ordinary service hardwood blocks are used as the brake lining, but for heavy duty asbestos-treated blocks are substituted.

These hoists are built in four sizes equipped with electric motors of 100, 150, 225 and 300 hp. respectively, these ratings being based on a rope speed of 400 ft. per minute.

Electric Tie Tamper

The latest form of the Jackson electric tie-tamping machine, made by the Electric Tamper & Equipment Co., Chicago, delivers about 60 strokes per second, each stroke having a force estimated at 600 lb. This tamper is said to work well in stone, gravel, sand and cinder ballast. The revolving element of the motor is mounted on a nickel-steel shaft running in ball bearings and having at one end an unbalanced weight which revolves at 3,600 r.p.m. and sets up powerful vibrations in that end of the motor casing to which the tamping bar is bolted. The handle is attached to the motor casing by spring plates.

In moving, the tamper is not lifted but is dragged, its weight being carried on the curved spring. Current is furnished by a portable plant having a 5-hp. gasoline engine belted to a 1½-kw. 110-volt motor. This power unit, weighing about 500 lb., will operate four tampers and such other track tools as bond drills and rail saws. With a 250-ft. electric cable work can be done for a distance of 500 ft. with one set-up of the power unit, but longer cables may be used.

Publications from the Construction Industry

Revolving Car-Dumper—WELLMAN-SEEVER-MORGAN Co., Cleveland, has issued an illustrated 8-p. bulletin on its revolving dumper for unloading railway freight cars of all sizes and capacities. The equipment consists of a cradle which, after the car has been clamped within it, revolves, dumping the contents in only a fraction of the time that would be required by other means of hand or mechanical unloading. The car-dumpers are designed for a normal capacity of 20 cars per hour.

Track Drainage—W. S. DICKEY CLAY MFG. Co., Kansas City, Mo., has issued a 60-p. booklet on the use of vitrified pipe for ordinary drainage of railway track, roadbed and yards, and also for the elimination of wet spots which make maintenance expensive. Numerous installations are illustrated. Incidentally the pamphlet deals with the use of this pipe for culverts, pile protection, well casing and small septic tanks at shops and stations.

Railway Station Heating—AMERICAN RADIATOR Co., Chicago, has issued a 16-p. illustrated pamphlet on the Ideal-Arcola boiler, radiator and hot-water circulating system specially designed for small railway stations which have no basement for a heating plant and where the agent is the only attendant. This system is applicable also for signal and interlocking towers and other small structures.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Construction Possibilities During the Coming Year

Probable Extent of 1924 Building Show
—Also Value of Plumbing, Heating, Lighting and Painting Jobs

With a \$6,000,000,000 building year drawing to a close, some idea of the 1924 construction prospect may be gained from the figures shown herewith.

Commercial buildings formed 30 per cent of the estimated 1923 total; industrial buildings 9 per cent; residential buildings, 28 per cent and other engineering construction exclusive of buildings, 33 per cent.

Based upon the above percentages, the probable extent of 1924 construction in the classes mentioned, will be as follows:

Streets and Roads.....	\$1,250,000,000
Industrial building.....	350,000,000
Commercial building.....	1,350,000,000
Residential building.....	250,000,000
Other construction.....	1,500,000,000

The money values of possible jobs in the estimated 1924 program will be as follows:

	Industrial Building	Commercial Building
Plumbing.....	\$1,750,000	\$27,000,000
Heating.....	12,600,000	67,250,000
Lighting.....	9,675,000	17,250,000
Painting.....	11,060,000	27,000,000

Present New York Building Wage Scale To Hold During 1924

The Building Trades Employers Association of New York City has decided to maintain during 1924 the same wage scale and bonus paid throughout 1923. A higher wage scale would perhaps hinder and in many cases block construction that is now needed. Present indications point toward intensive operations for the coming year. With increased activities in the construction lines ahead, there does not seem to be any likelihood of non-employment.

The United States Bureau of Labor reported in September that the cost of living this year was 75.4 per cent higher than 1914.

A table of wage increase over a period of nine years will show how this cost of living has been met and also how it has affected construction costs. The per cent increase in each trade since 1914, is shown as follows:

Kind of Labor	Daily Wage 1914	Daily Wage 1923	Per Cent Increase
Cement masons' laborers	\$2.62	\$7.50	186.2
Cement masons	3.00	10.00	100
Bricklayers' laborers	3.00	8.00	166.6
Bricklayers	6.00	12.00	100
Engineers, hoisting	6.00	12.00	100
Carpenters' (Bronx, Brooklyn, Queens)	4.50	10.00	122.2
Plasterers' laborers	3.75	8.50	161.5
Plasterers	5.50	12.00	118.1
Stone masons	4.80	12.00	150
Blacksmiths and riggers	4.00	9.50	137.5
Sheet metal workers	4.00	10.00	100
Painters	5.50	10.00	81.8
Scaffolding	5.50	10.00	81.8
Tile layers	5.50	10.00	81.8

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 347 to 356, are the following:

Power Station, Sumner, Wash., to Stone and Webster, Inc., \$1,060,000.

High School, Brooklyn, N. Y., to Turner Constr. Co., \$2,045,000.

Current Freight Rates Compared With 1921-22

Due almost entirely to reductions in freight rates, made both voluntarily and by order of the Interstate Commerce Commission, the freight bill of the people of this country was approximately \$431,000,000 less during the first eight months this year than it would have been if the rates existing during the corresponding period of 1921 had remained in effect.

Compared with the rates in effect during the first eight months of 1922, the freight bill this year represents to the shippers of this country a reduction of approximately \$282,750,000 due to the voluntary reduction on agricultural products that became effective on Jan. 1, 1922, to the general rate reduction of 10 per cent effective on July 1, 1922, and to a number of individual readjustments in freight rates.

These estimates, which are made by the Bureau of Railway Economics from reports filed by the carriers with the Interstate Commerce Commission, are based on the freight traffic transported by the carriers from Jan. 1 this year to Sept. 1, which has been the heaviest in history.

Business Briefs

Call money steady at 4½ per cent as of Dec. 21.

Time money market dull with rate at 5 per cent.

Commercial paper rate 5 per cent with very little in the market.

Foreign exchange declines. Sterling, \$4.34½; last week, \$4.36½; year ago, \$4.64½. Franc, \$0.0510½; last week, \$0.0530½; year ago, \$0.0743½. Lira, \$0.0431½; last week, \$0.0435; year ago, \$0.0512½.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for in Construction News, pp. 347 to 356, are the following:

Hotel, Minneapolis, Minn., Calhoun Beach Holding Co., \$1,300,000.

Apartment, New York, N. Y., I. Kraft, \$1,500,000.

Recent Unit Bids Throughout the Country

The accompanying table gives the accepted prices of materials and operations in various parts of the country taken from contracts awarded during the last month.

The unit bids form an index of construction costs in outlying districts. A thorough knowledge of cost conditions may be had by reviewing the bid prices published weekly in the Construction News section of *Engineering News-Record*.

UNIT BID PRICES ON MATERIALS AND OPERATIONS FROM RECENT CONTRACTS AWARDED

Where Located	E.N.R. Issue	Nature and Extent of Job	Unit Bid Price
Ala., Fayette	Nov. 22	Digging 2 mi. ditch, 10 ft. wide.....	\$147,000.00

Foreign Projects of Interest to Americans

A number of foreign construction projects which should be of interest to American engineers, contractors and manufacturers has been reported by the United States Department of Commerce. They are noted here, further information being available at the Bureau of Foreign and Domestic Commerce or its district co-operative offices, when a reference number is given.

Pipe Line company's official now in New York relative to the purchasing of supplies. American firms interested may secure this official's New York address and other information concerning the Colombian Concession. Reference No. Colombia 35XA.

Bids for railway construction is desired by South American country. The line is to connect two important cities. Bids close Jan. 20, 1924. Reference No. 113,170.

American contractor's service desired in Japan by the owner of a large building property. Contractors already at work in Japan may be interested. Reference No. 113,181.

Sugar mill to be constructed in a Brazilian State. The project will involve an expenditure of about \$200,000.

Canning factory for South American country. The machinery to be installed is to come from America, about \$60,000 worth. This may be a forerunner to an extensive outlay.

Wire nail factory for American branch house in Mexico. The president of the firm in question is desirous of receiving quotations on nail machinery of 2-ton per day capacity and information concerning nail-polishing machine. Reference No. 113,166.

Enlargement of waterworks and public building in Rumania. The municipal engineer of a city in Rumania is quoted in part as follows: At present the city would grant to an American contractor not only the constructing of the waterworks and canalization (sewage), but the building of the public market hall, the development of the electric plant and of the management of all this works. Reference No. 111,822.

Cold-storage plant for Brazil. The name of the company and the city where this plant is to be erected is available for interested American firms.

Public works planned by city in China as follows: street building, waterworks system, electric light and power plant. Finances of the municipality reported sound. Reference No. 815X.

Paving Brick Shipments Remain High

Considering seasonal influences, shipments of vitrified paving brick for November ran considerably above normal,—64 per cent of the industry's tonnage reporting total shipments of 21,689,000 according to a report just made to the U. S. Department of Commerce by the National Paving Brick Manufacturers Association. In October 66 per cent of the industry's tonnage reported shipments of 34,287,000.

Unfilled orders on hand declined from 64,531,000 for October to 54,535,000 for November. For the first time since last spring the total number of brick manufactured for the month ran greatly in excess of shipments indicating that companies are manufacturing for stock in anticipation of late winter and early spring shipments.

Future Transportation Needs

That the future transportation needs of the country have been thoroughly studied, is shown by recent reports of the Transportation Conference's Committee on Governmental Relations to Transportation. The committee reports that in the next ten years the freight volume will be one-third more than at present; passenger traffic one-fourth more. In order to meet this demand, there must be 38,350 additional miles of track; 13,200 more locomotives; 725,000 freight cars; 12,300 passenger cars. These additions will cost approximately \$5,339,874,000.

(Continued on p. 1080)

Recent Unit Bids on Large Bridge Contract

Bids were opened by State Highway Comm. at Trenton, N. J., Nov. 27, for a bridge over the Raritan River between Perth Amboy and South Amboy, N. J. (a) Stillman, Delehanty, Ferris Co., 1 Exchange Pl., Jersey City, (awarded contract); (b) F. Snare Corp., 114 Liberty St., New York; (c) P. McGovern, 50 East 42nd St., New York. This is Federal Aid Project No. 20, the main bridge consisting of 1,536 lin.ft. steel plate girder spans carried on concrete piers, supported on pile and faced with granite, and 360 ft. span. The unit bids are as follows:

	A	B	C
Necessary clearing of right-of-way, etc., complete (lump sum).....	\$4,973 00	\$14,000 00	\$28,000 00
3,418 cu.yd. excavation, roadway cut, north approach, including grading.....	3 50	2 00	6 25

Extended totals.....	\$3,702,922	\$3,728,645	\$3,862,847

Future Transportation Needs

(Concluded from p. 1079)

Motor trucks and buses have been recognized as legitimate supplements to railroad facilities and as such have been figured in the program to meet the country's future transportation needs. This will permit the railroads to discontinue a service which is not profitable and which can be more easily handled by motors.

Water transportation was also studied and is a part of the problem to be worked out.

Some figures which are of general interest has come from the work of this conference.

In 1921, the railroads paid \$277,000,000 in taxes and during this same period expended \$756,000,000 on maintenance. Electric railways paid \$92,000,000 in taxes and expended \$101,000,000 on maintenance for the same year.

If the motor trucks are to meet the requirements of the future, the states must see that highways are suitable for such traffic. The sources of the money used in the 1921 highway program

was studied and the committee summarized the situation as follows:

Bonds	\$417,817,208
General state and local taxation	381,091,542
Miscellaneous	88,919,158
Gasoline tax and registration	109,154,226
Federal and forest road aid	76,679,897
Total	\$1,071,662,031

The work of this conference has pointed the way to improvements in the present transportation system but back of it all—the idea—the country's good and need.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions and costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Dec. 6; the next, on Jan. 3.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.	\$3.64	\$4.00	\$4.40	\$3.30	\$3.55	\$4.20	\$3.60	—\$3.85	\$4.25

Common Labor:									
Common labor, union, hour.75	.35	.30@.50	.82	—40@.45	.50@.55	.55	.62 1/2
Common labor, non-union, hour.30	.30@.50	.82	—40@.45	.35@.50	.50	.62 1/2	.30

Explanation of Prices.—Prices are in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside; common lump lime, in 280-lb. bbl. net and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b.

Labor.—Concrete laborers' rate, 93¢; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Comment on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 1/8 x 8 x 1 1/2. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price.

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on white pine lumber, free on cars at mill. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.50). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 10 days from date of shipment. 6-in., \$119.

Weekly Review of the Market

Except for the usual holiday activity, a somewhat slower pace is noticeable in business, generally. A slight decrease in employment is reported among basic industries and a decline in freight loadings indicates the lessened volume of merchandise being handled. The slowness of pig-iron buying is just an instance of the attitude of buyers, who show a tendency to defer important commitments until the new year. Favorable indications, however, are

apparent in a 12 per cent increase in the estimated value of the year's agricultural output. This means increased buying power in that direction. Increased issuance of building permits indicates a continuation of the winter construction movement. Firmness of steel prices and maintenance of buying among railroads and automobile makers, are indicative of the trend of business expected at the beginning of the new year. November export figures were

higher than any other month this year.

A brief outline of the iron and steel situation follows: Pig-iron market very quiet. No. 2 foundry iron quoted as low as \$20@21 per ton at Birmingham. Iron and steel scrap buying active; prices tending upward. Tin plate demand fairly good; mills operating at 96 per cent of capacity. Fabricated structural steel prices still firm at \$2.50 for plates and shapes and \$2.40 per 100 lb. for bars, f.o.b. Pittsburgh.

CONSTRUCTION NEWS

Engineering News-Record, December 27, 1923

The Construction Barometer

Slower Pace in Industrial Activity—Production Conditions Exactly Opposite One Year Ago

THE reported slower pace in industrial activity is confirmed by the charted trends in iron, steel, lumber and cement production, as shown below. Pig-iron, steel ingot and lumber output declined considerably during November of this year, against an exactly opposite condition existing in November,

1922. From March to October, 1922, the unfilled steel tonnage steadily rose; during the same period this year it gradually dropped. Although unfilled tonnage declined during the last quarter of 1922, the drop from October to November of this year was unusually abrupt. Cement output, though lessened, conforms

closely to the regular seasonal trend. November debits to individual accounts (Federal Reserve) showed only a slight drop from the preceding month, against a sharper decline last year. Payments of debts are normally heavier in the last three months of the year than during the preceding quarter.

Gas Distribution System—Coffeeville, Ala. Plans election to vote on \$500,000 bonds for gas production and distribution system. T. R. Marshall, city engr.

Lighting System—St. Joseph, Mo.—Election in January to vote on \$500,000 bonds electric lighting system. W. K. Seitz, city engr. Noted Sept. 20.

Dock—South St. Louis (St. Louis P. O.) Mo.—Natl. Lead Co., International Life Bldg., St. Louis, plans terminal dock on Mississippi River, at Canary Plant, here. To exceed \$25,000.

Rock Crushing Plant—Colusa, Calif.—Colusa Sand and Rock Co., having plans prepared gravel and rock crushing plant, incl. spur tracks. Will install rock crusher, concrete bins, storage bins, motors, transformers and will probably be in market for dragline excavator.

Golf Course—Pasadena, Calif.—City plans election to vote on \$125,000 bonds for golf course.

Transmission Lines, etc.—Pasadena, Calif.—See "Industrial Works."

Ornamental Lighting System—San Fernando, Calif.—See "Streets and Roads."

Transmission Line—Quebec—Electric Service Corp., Power Bldg., Montreal, plans 4,400 volt transmission line in municipalities of St. Felix de Vallee and St. Jean de Matha, distance of 7 miles.

BIDS DESIRED

Dike, etc.—Los Angeles, Calif.—Petroleum Export Co., 423 Pacific Electric Bldg., receiving bids \$50 ft. rein-con. dike, 3 ft. high; one 50 x 100 ft. and one 50 x 75 ft. steel and corrugated iron warehouses, etc.

Wharf—Pembroke, Ont.—Jan. 9, by Dominion Pkys., Ottawa, reconstructing concrete bulkhead 689 ft. long, 100 ft. return wall, gravel fill, wharf slips, dredging basin and channel 70,000 cu.yd. sand, muck and clay, gravel road, moving existing concrete bulkhead, and old pilework repair approach 1,120 ft. long, \$100,000. K. M. Cameron, engr.

BIDS RECEIVED

Transmission Line, etc.—Brookton, Mass.—See "Industrial Works."

Heating and Ventilating Apparatus—Brooklyn, N. Y.—Bd. Educ., 500 Park Ave., New York, Dec. 19, heating and ventilating apparatus, in P. S. 99, East 9th St. between Aves. K and L, here, from Hills.

Heating and Ventilating Apparatus—Pittsburgh, Pa.—Bd. Educ., 500 Park Ave., New York, Dec. 19, heating and ventilating apparatus, in P. S. 142, Rapelye St., here, from D. J. Rice, 405 Lexington Ave., New York, \$46,970. Noted Dec. 20.

Heating and Ventilating Apparatus—New York, N. Y.—Bd. Educ., 500 Park Ave., Dec. 19, heating and ventilating apparatus in P. S. 60, 12th St. and Ave. A, from Raiser Heating Co., 39 Amsterdam Ave., \$98,765. Noted Dec. 20.

Pavilion—New York, N. Y.—Bellevue & Allied Hospital, 415 East 26th St., Dec. 20, general contract pavilions F and G of new Bellevue Hospital, from George A. Fuller Co., 949 Bway, \$2,940,700; heating work, from T. F. Hall, Inc., 405 Lexington Ave., \$260,716; plumbing, from T. E. O'Brien, Inc., 631 5th Ave., Brooklyn, \$448,000. Noted Nov. 29.

CONTRACTS AWARDED

Car Sheds—Wichita Falls, Tex.—Wichita Tract, concrete and brick car sheds, to C. M. Balkowski, Morgan Bldg., \$40,000.

Tunnel—Nagura, Falls, Ont.—Queen Victoria Park Comm., extending scenic tunnel under Horse Shoe Falls, here, to J. H. McKnight Co., 88 St. David St., Toronto, \$36,000, also 2 concrete bridges at Dufferin Islands, to R. McKnight, 86 Clinton Ave., Toronto, \$21,000.

Materials and Equipment

PROPOSED WORK

Tractor—Utica, N. Y.—Park Bd. plans to purchase tractor and equipment, \$3,000.

Gravel Machinery—Wisconsin—Following are county appropriations for road machinery during 1924. Sawyer Co., \$4,000 incl. 3 light trucks, patrol graders, etc.; E. J. Kelly, Hayward, Wis., for Outacoma Co., \$20,000 incl. larger grader, small tools, etc.; G. Bruzewitz, Appleton, comr.; Waushara Co., \$27,500 incl. tractor and crushing outfit; Waubesa, Wis., comr. George A. Fuller Co., \$10,000, incl. 3 patrol graders, one 12 ft. blade with back sloper and ditcher.

Road Machinery—Arendia, Fla.—The Sota Co., Jacksonville, to vote on \$10,000 bonds for road building machinery.

Structural Steel—Chicago, Ill.—Illinois Central R. R., 125 East 11th Pl., plans to purchase 350 tons structural steel for bridge. F. L. Thompson, ch. engr.

Road Machinery—Hudson, Wis.—St. Croix Co. appropriated \$10,000 for road machinery, incl. patrol graders, J. Caffrey, Hammond, comr.

Road Machinery—Mantowau, Wis.—Mantowau Co. takes bids about Feb. 1, 2 motor trucks, 1 patrol tractor, 1 patrol grader, 1 heavy grader and 5 wheel

scrapers. \$25,000. J. Connell, highway comr.

Dragline Excavator—Colusa, Calif.—See "Unclassified."

BIDS DESIRED

Pipe, etc.—Phila. Pa.—Dec. 31, by T. F. Armstrong, purch. agt., 312 City Hall, furnishing lengths c. pipe, Class 112, 50,000 lbs. pig lead, Class 111, fire hydrants, Class 113, all foregoing for Water Bureau, 175,000 gal. fuel oil, Class 115, 6,500 cu.yd. asphalt, 2,500 tons crushed slag, 2,500 tons binder stone, Class 116, etc., for Bureau of Highways.

Dredge—Savannah, Ga.—Jan. 10, by Comrs. Chatham, Ga., and ex-officio judges, furnishing land dredge.

Tractor, etc.—Pass Christian, Miss.—Dec. 31, by Bd. Supervs. Harrison Co., Court House, one crawler type tractor and one 7 ft. grader with needed outfit.

Gravel—Abbeville, La.—Jan. 2, by J. E. Broussard, pres. Police Jury Vermillion Parish, 13,000 cu.yd. washed gravel and 5,000 cu.yd. sand and gravel, 40% metal retained on 1 in. sieve.

Tractor and Shovel—Granite City, Ill.—F. J. Lewis Mfg. Co. in market for caterpillar tractor and shovel, complete outfit.

Cement—Wisconsin—Jan. 3, by State Hy. Comrs., Madison, Wis., 1,024,000 bbl. Portland cement for delivery during 1924. A. R. Hirst, state highway engr.

Clam Loader—Pittsburg, Kan.—Du Bois Constr. Co., in market for clam loader for handling sand, gravel and crushed rock.

Crushed Stone—Houston, Tex.—Jan. 7, by Comrs. Court Harris Co., 10,000 tons crushed stone, 10,000 tons gravel, 5,000 cu. yd. sand and gravel, 100 tons crushed rock, \$50,000. Howe & Wise, co. engrs.

Crushing plant, etc.—Salado, Tex.—L. Harrington & Co., engrs., Houston Bldg., San Antonio, receiving bids and opens same about Jan. 10, for new crushing plant, incl. 75 hp. pumper, screens and bins, 300 yd. sand washer, 75-100 hp. boiler, bucket line probably 2 yd. slide, hoisting engine and conveyor, to J. E. Salado, Salado, Tex. Noted Dec. 20 under "Industrial Works."

Paving Mixer—Okmulgee, Okla.—J. E. Parks Construction, receiving bids large steam concrete paving mixer.

BIDS RECEIVED

Pipe—Montreal, Que.—Furnishing 207 tons 20 in. and 71.5 tons 16 in. pipe for spring delivery and 535 tons 20 in., 256.1 tons 16 in. and 568.75 tons 30 in. pipe for winter delivery, from Kennedy & Co., 288 Beaver Hill Bldg., \$650 per ton.

CONTRACTS AWARDED

Inorganic Dust, etc.—Brooklyn, N. Y.—E. Riegler & Sons, pres. Boro Hall, 1,200 tons inorganic dust, to Limestone Products Corp. of America, 17 West 42nd St., New York, \$6,420; 6,000 cu.yd. asphalt sand, to A. B. Mott, 100 Broadway, \$1,000; 100 tons \$7,800; 2,500 cu.yd. gravel or broken stone, to Rosoff Sand & Gravel Corp., 152 West 42nd St., New York, \$6,125. Noted Nov. 29.

Lumber—Plank, Ia.—Carr Co., furnishing 300,000 ft. bridge lumber and 17,000 ft. red cedar to Standard Bridge Co., City National Bank Bldg., Omaha, Neb., \$27.22. Noted Nov. 22.

Lumber—Marengo, Ia.—Iowa Co., 240,000 ft. bridge lumber, to Wheeler Lumber St., Des Moines, \$37. Noted Nov. 29.

Bridge and Supply Co., 200 Southwest 9th Steel Bars, etc.—Mann City, Ia.—Cerro Gordo Co., 100 tons 8 in. round steel reinforcing bars and 3,024 ft. 12 in. corrugated metal culvert to Ft. Dodge Culvert and Steel Co., Ft. Dodge, \$3.15 per cwt. Noted Nov. 29.

Plank and Piling—Onawa, Ia.—Monona Co., 5 cars full sawn fir bridge plank and 1 car cedar piling to Blencoe Farmers Elevator Co., Wadena, \$39.50, piling \$1.50. Noted Nov. 29.

Bridge Material—Vinton, Ia.—Benton Co., 120,000 ft. No. 1 rough fir bridge lumber, to W. W. Saylor, Waverly, \$39.

Crushed Rock—Portland, Ore.—Furnishing crushed rock gravel, etc., (1) at contractors' bunkers (2) delivered at city paving plant to City Motor Trucking Co., 291 Hawthorne Bldg., (1) 500 cu.yd. 3 in. and 500 cu.yd. 1 in. crushed rock \$1.80, 100 cu.yd. 2 in. crushed gravel \$1.20, 200 cu.yd. rock screenings \$2.20, 200 cu.yd. concrete sand and 200 cu.yd. mason sand \$1; (2) 500 cu.yd. 3 in. and 5,800 cu.yd. 1 in. crushed rock \$1.75, 900 cu.yd. crushed gravel \$1.2, 2,980 cu.yd. rock screenings \$1.90, 800 cu.yd. concrete sand and \$0.90 and 7,780 cu.yd. masons sand \$0.95.

Steel Pipe—San Bernardino, Calif.—Furnishing 6,000 lin.ft. 4 in. and 5,000 lin.ft. 3 in. wrought steel pipe to Mark & Kelly Co., 2nd and Clement Sts., San Francisco, \$51 and \$31.10 respectively.

OFFICIAL PROPOSALS

Bids: Jan. 15.

Municipal Water Supply Improvement

Oklahoma City, Okla.

Sealed bids will be received by M. Peshek, Jr., City Clerk of the City of Oklahoma City, Oklahoma, up to 12.00 o'clock noon, Tuesday, January 15th, 1924, and a duplicate of each bid must be filed with the City Auditor of the said city, and will be opened and considered by the Board of Commissioners 2.00 o'clock p.m., Tuesday, January 15th, 1924, for the construction of the following work for the improvement to the municipal water supply for the City of Oklahoma City, Oklahoma:

Section A—1—Ambursen Const. Co. plan
—Main Dam Extension.
Section A—2—Ambursen Const. Co. plan
—Intake.

Section A—3—Ambursen Const. Co. plan
—Gates and Operating Mechanism. Main Dam Extension.
Section A—4—Ambursen Const. Co. plan
—Steel Flashboards and Operating Mechanism. Intake.

Section B—1—V. V. Long & Co. plan
—Main Dam Extension.
Section B—2—V. V. Long & Co. plan
—Intake.

Section B—3—V. V. Long & Co. plan
—Structural Steel Crest, Intake.
Section C—1—Callahan Const. Co. plan
—Main Dam Extension.

Section C—2—Callahan Const. Co. plan
—Intake.
Section C—3—Callahan Const. Co. plan
—Gates and Operating Mechanism—Main Dam Extension.

Section C—4—Callahan Const. Co. plan
—Gates and Operating Mechanism, Intake.
Section D—1—Holway Engr. Co. plan
—Main Dam Extension.

Section D—2—Holway Engr. Co. plan
—Intake.
Section D—3—Holway Engr. Co. plan
—Gates and Operating Mechanism—Main Dam Extension.

Section D—4—Holway Engr. Co. plan
—Gates and Operating Mechanism—Intake.

Bids will be considered on each Section separately, and contractors may bid on any or all sections. All of the necessary work and materials used shall be in strict accordance with the plans and specifications therefor, now on file in the office of the City Clerk.

Each bidder shall accompany his bid with a sworn statement in writing that the bidder had not directly nor indirectly made any agreement, express or implied, with any other bidder or bidders, having for its object the controlling of the price or amount of such bid or bids, the limiting of the bidder or bidders, the parcelling or farming out to any bidder or bidders, or other persons, of any part of the contract, or any part of the subject matter of the bid or bids, the reducing of time or the knowledge of the amount, kind or character of any bid to be made by any other person, firm or corporation, except those submitted and filed by him.

The bid or bids filed with the City Clerk must be accompanied by a certified check on any national bank, in the sum of at least five (5%) per cent of the amount of the bid or bids.

It being further understood that the amount of damages which the City would suffer would be impracticable to determine and extremely difficult to fix in case the successful bidder should fail to enter into a contract and give the required bonds within the required time it is therefore understood that by the filing of a bid or bids it will be considered an agreed that

OFFICIAL PROPOSALS

the amount of damages which the City would suffer by reason of such failure on the part of said successful bidder is the amount represented by the check or checks so filed by the successful bidder, and that the City shall have the authority to appropriate such checks for its own use and benefit in payment for such damages.

Each bidder shall agree to enter into a contract and furnish the required bonds within ten (10) days after the acceptance of his bid, and shall state in his bid when he will begin the work and when he will complete the same.

The contractor will be required to give bond in the sum of twenty-five (25%) per cent of the contract price for faithful performance of the work, and all other bonds that are required by the laws of the State of Oklahoma or the ordinances of said City, and to give bond to hold the City harmless from any and all damages for which the City might be liable under the law, and which might occur by reason of any act upon the part of the said contractor or of any of his employees.

A deposit of fifty (\$50.00) dollars will be required for each set of plans and specifications. Such deposit will be refunded upon the return of the plans and specifications in good condition within 10 days after the bids are opened.

Each bidder is hereby notified that the Ambursen Co. plans, the V. V. Long & Co. plans, the Callahan Const. Co. plans and the Holway Engr. Co. plans are different plans for the same construction work and the City reserves the right to finally adopt for said work any one plan or any part of any plan.

The Board of Commissioners further reserves the right to reject any or all bids.

M. PESHEK, JR.,
City Clerk.

Bids Jan. 5

Fire Escapes

Sonyea, N. Y.

Sealed proposals for Construction—Fire Escapes, at Craig Colony, Sonyea, N. Y., will be received by Mr. Percival L. Lank, President, Board of Managers, Craig Colony, Sonyea, N. Y., until 2 o'clock p.m. on Tuesday, January 8, 1924, when they will be publicly opened and read. Proposal must be enclosed in an envelope furnished by the State Architect, sealed and addressed and shall be accompanied by a deposit consisting of a certified check drawn upon some legally incorporated bank in this State and made payable to the State of New York, or money, equal to five per cent (5%) of the amount of the proposal. The contractor to whom the award is made will be required to furnish surety company bond in the sum of fifty per cent (50%) of the amount of contract within thirty (30) days after receipt of notice of award of contract and in accordance with the terms of Specification No. 4182. The right is reserved to reject any or all bids. Drawings and specifications may be examined at the Craig Colony, Sonyea, N. Y., at the Department of Architecture, 18th Floor, Fuller Bldg., Broadway and 23rd Street, and at the Department of Architecture, Capitol, Albany, N. Y. Drawings, specifications and blank forms of proposal may be obtained at the Department of Architecture, Capitol, Albany, N. Y., upon application to the State Architect, Sullivan W. Jones, Capitol, Albany, N. Y. Dated: December 13, 1923.

OFFICIAL PROPOSALS

Bids: Jan. 18.

Dredging

ENGINEERING DEPARTMENT
PARISH OF CALCASIEU, LOUISIANA

Lake Charles, La.

December 15th, 1923.

Sealed bids will be received by the Police Jury of the Parish of Calcasieu, Louisiana, until noon, Friday, January 18th, 1924, in the Police Jury Room, Court House, Lake Charles, Louisiana, and then and there publicly opened, for the construction of a Navigational Channel 30 feet deep by 125 feet wide at the bottom, from Lake Charles to the Sabine River.

SECTION 3

The construction of a channel 30 feet deep and 125 feet wide at the bottom, from Station 714, East along the Intracoastal Canal, to Station 580. A distance of 2.54 miles. Approximately 2,020,000 cubic yards of earth to be moved.

This work is along the present Intracoastal Canal, which on this section, is 6 feet deep and 40 feet wide on the bottom. The Atlantic, Gulf and Pacific Dredging Company have a contract with the War Department to deepen and widen this part of the Intracoastal Canal to 12 by 90 feet; their dredge "TEXAS" is working about Station 760 at present, and will pass Station 714 going East between January 1st and 10th. From Station 714, East to Station 680, the land is marsh, elevation +1.0 to +2.0. The Gum Cove Ridge lies between Station 680 and 580, elevation +2.0 to +12.0. Average stage of water +1.2. All depths and elevations refer to Mean Low Gulf Datum.

SECTION 5

The construction of a channel 30 feet deep and 125 feet wide at the bottom, from Station 58 on the Intracoastal Canal, West to Station 322. A distance of 5 miles. Approximately 3,480,000 cubic yards of earth to be moved.

This work is along the present Intracoastal Canal, which has been deepened and widened from Station 58 to 120 to 12 feet deep by 90 feet wide on the bottom. From Station 120 to 322 the Canal is 6 feet deep by 40 feet wide on the bottom, with a Pilot cut from Station 175 to 322, 12 feet deep by 40 feet wide on the bottom, along the South side of the old ditch. The Government Dredge "BLACKWATER" is at present at Station 120 working West completing the Canal to 12 feet depth and 90 feet wide. The Blackwater will probably pass Station 175 about February 1st. From Station 58 to 90 is a low ridge. Elevation +2.0 to +7.0; from Station 90 to Station 322 is a Black Grass Marsh, with knolls; Elevation +1.0 to +3.0. Average stage of water +1.2. All elevations and depths refer to Mean Low Gulf Datum.

Every bid shall be accompanied by a certified check in an amount equal to five per cent (5%) of the amount of the bid, payable to the Treasurer of Calcasieu Parish, which check shall be forfeited to the Parish should the bidder to whom such contract is awarded fail to enter into the contract required within ten (10) days after notice to do so from the Police Jury of Calcasieu Parish.

The Police Jury reserves the right to reject any or all bids.

V. R. REEVES,
President, Police Jury.
FRID SHUTTS,
Parish Engineer.

OFFICIAL PROPOSALS

Bids: Jan. 17.

Excavation and Rock ProtectionSTATE OF NEW YORK
DEPARTMENT OF PUBLIC WORKS
BUREAU OF CANALS

Albany, N. Y.

December 13, 1923.

Sealed proposals will be received by the undersigned at his office in Albany, N. Y., until twelve o'clock noon of Thursday, January 17th, 1924, at which place and hour they will be publicly opened and read, for improving the New York State canals pursuant to the provisions of Chapter 147 of the Laws of 1903, and of the acts amendatory thereof and supplementary thereto, and Chapter 570 of the Laws of 1915, as follows:

CONTRACT NO. 214.

Erie Canal—Section 9.

For completing the excavation of the canal channel in the Genesee river at Rochester and placing rock spoil protection along the river banks.

Sheets 1 to 3, inclusive.

Plans may be seen, and detailed specifications, engineers' estimates of quantities, proposal blanks, form of contract and bonds required and other information for proposers may be had at the office of the Bureau of Canals, Albany, N. Y.; at the office of the Division Engineer, Department of Public Works, Utica, Syracuse, Rochester and Buffalo; and at the Terminal Warehouse, Pier 6, East River, New York City.

Blueprint copies of plans will be furnished by the State Engineer and Surveyor upon the receipt at his office in the Telephone Building, Albany, N. Y., of payment at the rate of fifteen cents (15c) per sheet. Refund will not be made for any blueprints which may be returned.

Monthly estimates will be paid of ninety per centum (90 per cent) of the work done at the contract price. Every proposal for said work must be accompanied by a money deposit in the form of a draft or certified check upon some good banking institution in the city of Albany or New York, issued by a national or state bank, in good credit within the State and payable at sight to the Commissioner of Canals and Waterways for five per centum (5 per cent) of the amount of the proposal.

The person whose proposal shall be accepted will be required to execute a contract and furnish bonds within ten days from the date of notice of award delivered to him or them in person or mailed to the address given in the proposal.

Upon execution of the contract and approval of bonds the certified check or draft will be returned to the proposer unless the same shall have been presented for collection prior to such time in which case the amount of the deposit will be refunded by the Commissioner of Canals and Waterways.

The deposits of bidders other than the one to whom the award of contract shall be made will be returned immediately after the award has been made.

The bond required for the faithful performance of the contract shall be in such sum as shall be fixed by the Commissioner of Canals and Waterways, which sum shall not be less than twenty per centum (20 per cent) of the estimated cost of the work, according to the contract price, and an additional bond known as the labor bond, in the sum of ten per centum (10 per cent) of the amount of the estimated cost of the work according to the contract price, will be required as security that the contractor will pay in full at least once in each month all laborers employed by him upon the work specified to be done in the contract.

In the event that more than one surety company is offered as surety on said bonds no insurance only will be accepted.

Each proposal must be addressed to the Bureau of Canals, State Department of Public Works, Albany, N. Y., and must be endorsed on the envelope with the name of

OFFICIAL PROPOSALS

the construction for which the proposal is made.

Award, if made, will be made to the person or persons whose proposal shall be lowest in cost to the State for doing the work, and which shall comply with all provisions required to render it formal. Before any award shall be made the lowest bidder will be required to satisfy the Commissioner of Canals and Waterways of his ability to provide suitable equipment and materials for the proper performance of the work.

The right is reserved to reject all proposals and to award the work on a contract in the regular manner if, in the judgment of the undersigned, the interests of the State will be enhanced thereby.

ROBERT L. FULLER,
Commissioner of Canals
and Waterways.

Bids: Jan. 3.

**Railroad Siding, Relocating
Electric Railroad and Bridge**

Kansas City, Mo.

Sealed proposals will be received by the Purchasing Agent of Kansas City, Missouri, at the office of the Purchasing Agent, Second Floor, City Hall, until 2 o'clock p.m., January 3, 1924, for furnishing the labor and materials and erecting a certified railroad siding about three-fourths of a mile long, and a relocated electric railroad and highway about four-fifths of a mile long including a reinforced concrete highway bridge, span 16 feet, width 18 feet, located just north of North Kansas City. The proposals shall be in accordance with drawings and specifications on file in the office of the Board of Fire and Water Commissioners of Kansas City, Missouri, of Fuller and Maitland, Engineers for the Board of Fire and Water Commissioners, 600 Walnut Street, Kansas City, Missouri, and of Fuller and McClintock, 170 Broadway, New York City. Copies of the drawings and specifications may be obtained from Fuller and Maitland, 600 Walnut Street, Kansas City, Missouri, upon the deposit of \$10.00 for each set, which deposit will be refunded provided the drawings and specifications are returned in good condition within 30 days after bids are received.

Each bidder shall deposit with the City Comptroller a certified check on a solvent bank or trust company in the amount of five thousand dollars (\$5,000), payable to the City Comptroller of Kansas City, Missouri, and accompany his bid with the Comptroller's receipt therefor. The certified check is required as a guarantee that the bidder will, within ten (10) days after receiving the award of the contract, file with the City a satisfactory bond to the amount of fifty per cent of the bid price, and will execute the contract.

The Board of Fire and Water Commissioners does not bind itself to accept the lowest or any bid offered, and reserves the right to reject any or all bids, and to waive any irregularity or informality in the bids.

MARTY H. RAMING,

Purchasing Agent,
Fuller and Maitland,
Engineers.By Authority of the Board of Fire and
Water Commissioners.

Bids: Feb. 4, 1924.

University Buildings

Urbana, Ill.

Sealed proposals for General Work on four buildings to be erected for the University of Illinois in Urbana, Illinois, will be received at the James H. White, Supervising Architect, 255 Administration Building, Urbana, up to 2:00 p.m., Monday, February 4, 1924.

Bidders interested should write the Supervising Architect immediately for information as to type and size of buildings and dates when plans will be available.

OFFICIAL PROPOSALS

Bids: Jan. 3.

Sewer Construction

McKenzie, Tenn.

Sealed bids for the construction of a vitrified pipe sewer system and settling tanks for the City of McKenzie will be received by the Mayor and City Council at the office of H. C. Bryant, City Clerk until 2 p.m., January 3, 1924, at which time and place they will be opened and publicly read. The approximate quantities are as follows:

33,506 Linear feet 8" Sewers
4,920 Linear feet 10" Sewers
900 Linear feet 12" Sewers
1,650 Linear feet 15" Sewers
134 Manholes
12 Flush Panks

588 Linear feet vertical risers

2 Reinforced concrete settling tanks

Plans and specifications may be examined at the office of H. C. Bryant, City Clerk, at McKenzie, or at the office of the Engineer, or a copy may be obtained from the Engineer upon receipt of a deposit of \$5.00, of which amount \$3.00 will be refunded when the plans and specifications are returned in good condition. If additional information is required, address the Engineer.

The right is reserved to reject any and all proposals and to waive informalities. The contractor will be paid cash on monthly estimates amounting to 85% of the work done.

All proposals and bids must be accompanied by a certified check drawn on a responsible bank or trust company, and made payable to H. C. Bryant, City Clerk, for a sum of not less than 5% of the amount of the proposal; or a bidders bond for the same amount by a surety company authorized to do business in the State of Tennessee, will be accepted. The successful bidders will be required to furnish a performance bond in the sum of 50% of the contract price.

December, 1923.

H. C. BRYANT,

City Clerk.

B. H. KLYCE, Engineer,
506 4th and 1st Natl. Bank Bldg.,
Nashville, Tenn.

Bids: Jan. 19.

Pipe Line, Tunnel, Dam, Etc.

Charlottesville, Va.

Sealed proposals will be received by the City Manager at his office, Charlottesville, Va., until 11 o'clock a.m., January 19th, for the construction of approximately 12 miles of 18 inch Cast Iron Pipe Line and 700 linear feet of 4 x 6 Tunnel, a Diversion Dam, Grit Chamber and Regulating works. Plans and Specifications will be furnished by the City of Charlottesville, f.o.b. cars. Plans and Specifications can be seen on or after January 1, 1924, at the office of the City Manager, Charlottesville, Va., and at the offices of the Engineers, Fuller and McClintock, 170 Broadway, New York City, or Lee H. Williamson, National Bank Building, Charlottesville, Va. Proposal blanks will be forwarded upon application to the City Manager. Construction Bond to the amount of the contract will be required and each proposal must be accompanied by a certified check for \$10,000.00.

Arrangements for inspection of the line can be made at the office of Lee H. Williamson, National Bank Building, Charlottesville, Va.

The right is reserved by the City Manager to reject any or all bids.

BOYD A. BENNETT,
City Manager,
City of Charlottesville, Va.**Hauling Contracts Wanted**

Good work, Material Handling, etc. Have several fleets of trucks ready for service anywhere. No job too large. Special contracting for any kind of truck hauling or unloading. Unlimited references. Glad to estimate.

Construction of Flood Control Works

OFFICE OF THE BOARD OF DIRECTORS
THE PUEBLO CONSERVANCY
DISTRICT

Pueblo, Colo.

Dec. 17, 1923.

Sealed proposals will be received by The Pueblo Conservancy District, Pueblo, Colorado, until 2 o'clock, p.m., on Tuesday, January fifteen, 1924, for the construction of a relocated river channel and the relocation of 35 miles of railroad yard tracks in and about the barrier dam 6 miles west of Pueblo, involving approximately the following principal quantities divided into contracts as follows:

No. 1. Channel Excavation above Santa Fe avenue; material used in Railroad Yard and Levee Fills.
Upper railroad fill.....464,000 Cu.Yds.
Lower railroad fill.....30,000 Cu.Yds.
Levees.....486,500 Cu.Yds.
No. 2. Concrete Levee Paving.
Steel sheet piling.....74,400 Sq.Ft.
Concrete slab revetment.....26,600 Cu.Yds.
No. 3. Track Construction below Dry Creek Bridge.
Track laying and surfacing.....26.47 MI.
Alterations to tracks.....3.53 MI.
Rails and ties to be furnished to Contractor.)

No. 4. Channel Excavation, below Santa Fe avenue, 54,000 Cu.Yds.

No. 5. Concrete Intake Structure, Reinforced concrete, 350 Cu.Yds. Reinforced concrete pipe, 48" Diam., 808 lin ft.

No. 7. Retaining walls in Levee at Grand Avenue and at Union Depot, concrete, 1,985 Cu.Yds.

No. 8. Dyke below Santa Fe avenue, 6,000 Cu.Yds.

No. 9. Dykes at Dry Creek, 25,000 Cu.Yds.

No. 10. Dykes at North Side Water Works Reservoirs, 55,000 Cu.Yds.

No. 12. Railroad Track Removal, Removing and storing track materials, 32 miles.

No. 13. Railroad Embankment, above Dry Creek, Embankment, 130,000 Cu.Yds.; Riprap, 1,600 Cu.Yds.

No. 14. Railroad Track Construction above Dry Creek, Track laying and surfacing, 3.86 miles. (Rail and ties to be furnished to Contractor.)

No. 17. Concrete Culvert, North Side Water Works, Reinforced concrete, 139 Cu.Yds.; Timber flume, 60 MBM.

No. 18. Concrete Culvert, South Side Water Works, Reinforced concrete, 64 Cu.Yds.; Timber flume, 16 MBM.

No. 21. Upper Railroad Bridge, Substructure; concrete, 2,000 Cu.Yds.

No. 22a. Upper Railroad Bridge, Superstructure, 4-100 foot double track, through riveted truss spans. Structural steel, fabrication and delivery, 1,750,000 lbs.

No. 22b. Upper Railroad Bridge, Superstructure, 4-100 foot double track, through riveted truss spans. Structural steel erection, 1,750,000 lbs. Deck timber, 80 MBM.

No. 23. Concrete Railroad Bridge at Dry Creek, Reinforced concrete, through girders. Reinforced concrete, 4,800 Cu.Yds.

No. 30. Lower Railroad Bridge, Substructure, Concrete, 2,420 Cu.Yds.

No. 31a. Lower Railroad Bridge, Superstructure, 2-200 foot double track through riveted truss spans, skewed. Structural steel, fabrication and delivery, 2,500,000 lbs.

No. 31b. Lower Railroad Bridge, Superstructure, Structural steel, erection, 2-500,000 lbs.; deck timbers, 80 MBM.

OFFICIAL PROPOSALS

No. 32. Santa Fe Avenue Highway Bridge, Substructure, Concrete, 325 Cu.Yds.; Steel tubes for cylinder piers, 4.

No. 33a. Santa Fe Avenue Highway Bridge, Superstructure, 1-280 foot through riveted highway span. Structural steel, fabrication and delivery, 615,000 lbs.

No. 33b. Santa Fe Avenue Highway Bridge, Superstructure, Structural steel, erection, 615,000 lbs.; Deck timber, 50 MBM.

No. 34. Rock Canyon Barrier, Embankment, Earth fill, 90,000 Cu.Yds.

No. 35. Rock Canyon Barrier, Concrete, Plain concrete, 5,000 Cu.Yds.; Reinforced concrete, 7,328 Cu.Yds., which works are a part of the system of flood control and stream elimination for The Pueblo Conservancy District, to be carried out under authority of The Conservancy Act of Colorado, and are in accordance with the Official Plan of the District.

The contracts will include, in addition to the principal quantities given, incidental work, such as excavation, backfill, track material, etc. Cement reinforcing steel and track material will be furnished to the Contractor. Other contracts necessary for the completion of the project have been determined.

Proposals must be on the blank forms furnished by the Board, and must be accompanied by a certified check for not less than 5 per cent of the aggregate amount of the bid, figured on the basis of the estimated quantities and the unit prices bid, but which in no case shall be less than \$1,000 or need be more than \$50,000, such check to be drawn in the order of The Pueblo Conservancy District, as a guarantee that the bidder, if awarded a contract, will, within 15 days after the contract is delivered, or to his order, for the purpose of the same and furnish surety bond for the faithful performance of the contract in the sum of 55 per cent of the contract price; said contract and bond to be on the standard form adopted by the Board. A bidder submitting alternative bids may furnish a single certified check covering the largest amount required by any alternative.

If any bidder to whom an award has been made, shall fail to execute the contract or to furnish satisfactory bond within the time hereinbefore specified, or as extended by the Board, the award shall thereupon become void, in which case the proceeds of the certified check shall become the property of the District, and the contract may be awarded to the next lowest bidder, and such next lowest bidder or best bidder shall thereupon assume the contract, as if he were the party to whom the award was first made.

Each bidder must, in his proposal, present satisfactory evidence that he has been engaged in constructing works of the general character covered by his proposal, and that he is fully prepared, and has the necessary capital, to begin the work promptly, and to conduct it as required by the contract and specifications.

The bids are required to reject any or all bids, and to waive any technical defects, as the interests of the District may require. Drawings, specifications, proposal blanks, and other information may be obtained on application to the Chief Engineer, The Pueblo Conservancy District, Pueblo, Colorado, at whose office drawings, borings and other data may be inspected. This information is now on file for examination and will be ready for mailing on or before January first. Specifications, drawings, sample blank forms and proposal forms containing any one contract will be furnished for \$1.00, or all contracts for \$15.00.

Bids should be sealed and marked "Bid on Pueblo Conservancy Contract," and inclosed in a envelope addressed to Mr. W. Lee, Room 740, First National Bank

OFFICIAL PROPOSALS

Buildg., Pueblo, Colorado, or presented in person at the time of the letting. Bids will be opened by the Board, in the Council Chamber, at the City Hall, Pueblo, at 2 p.m., Tuesday, January 15, 1924.

Done this 17th day of December, 1923, at Pueblo, Colorado, pursuant to resolution of the Board of Directors of The Pueblo Conservancy District.

E. D. SPRUILL,
Secretary.

Bids: Jan. 16.

(READY TO RECEIVE)

Delaware River Bridge

CONTRACTS NOS. 9A, 9B, 9D, 10A & 10B
DEMOLITION

Philadelphia, Pa.

Sealed proposals for the demolition and removal of the buildings on the site of the Philadelphia approach between Front Street and Third Street, and between Fourth Street and Sixth Street, and the buildings on the site of the Camden Approach between Delaware Avenue and Fourth Street, will be received by the Delaware River Bridge Joint Commission at Room 806, Widener Building, Philadelphia, Pa., until 2:30 o'clock p.m., January 16, 1924, when they will be publicly opened and read. The contracts will be awarded, or all bids rejected, within fourteen days after bids are opened. The right is reserved to reject any or all bids.

Separate bids are asked for each of three sections of the Philadelphia Approach, and each of two sections of the Camden Approach. The work includes the demolition and removal of structures and certain other work incidental thereto. The work under Contracts 9A, 9B, 10A and 10B, is to be completed in three months, and that under 9D in six months.

Bids must be made upon the blank proposal forms, which together with specifications, bond and contract form, and contract drawings, may be obtained at the office of the Joint Commission, upon deposit of \$10.00, which deposit will be refunded upon receipt of bid or upon the return in good condition of the copies so taken.

Each proposal must be accompanied by a certified check for Three Thousand Dollars, drawn upon a national or state bank or trust company, having an office either in Philadelphia or Camden, and payable to the Delaware River Bridge Joint Commission, and surety's consent must be shown. The bidder or bidders to whom the contract for each section is awarded will be required to give bond in the sum of fifty per cent of the amount of such contract, but not less than \$25,000.

Delaware River Bridge Joint Commission.
GIFFORD PINCHOT, Chairman.
JOSEPH K. COSTELLO, Jr., Secretary.

Bids: Jan. 29

Street Paving

Baton Rouge, La.

Sealed bids will be received by the Commission Council, Baton Rouge, La., until 10 o'clock, Monday, Jan. 29th, 1924, for paving sixteen streets. Bids will be received upon Asphaltic Concrete, Brick, Sheet Asphalt, and Warrentite Bitulith, all on concrete base.

Approximate Quantities:
102,263 sq.yds. surfacing and base.
20,311 lin ft. straight curb and gutter.
10,272 lin ft. base excavation.
2,852 lin ft. circular curb and gutter.
3,976 lin ft. drain pipe, 10 inch.
2,915 lin ft. drain pipe, 12 inch.
150 lin ft. drain pipe, 15 inch.
140 lin ft. drain pipe, 18 inch.
56 catch basins.
3 manholes.
2,180 lin ft. stone header.
27,650 cu.yds. excavation.

Plans and specifications are on file in the office of the Consulting Engineer, City Hall, Baton Rouge, La. Copies may be had upon payment of fifteen dollars, which will not be returned.

A certified check, or bidder's bond, for 5% of amount bid, payable to the Commissioner of Finance, City of Baton Rouge, must accompany each bid. The right is reserved to reject any and all bids.
J. W. BILLINGSLEY,
Consulting Engineer.

Ask Your Wife—She Knows

Put on a sale of anything where either the price is reduced or the quantity and quality increased and there will be an athletic response by the women of the household. Just say this to your wife: "All insurance costs the same but some brokers give greater value by intelligent investigation than either increased cost or reduced premium. Which is the better buy?" Then when she gives you her answer telephone Swart for information regarding investigation that won't cost you a dime and will prove that.

OFFICIAL PROPOSALS

Bids: Jan. 10.

Land DredgeOFFICE OF THE COMMISSIONERS OF
CHATHAM COUNTY AND EX-OFFICIO
JUDGES
Savannah, Georgia.

December 13, 1923.
Sealed proposals will be received by the Commissioners of Chatham County and ex-officio Judges until the 10th day of January, 1924, at 12:30 o'clock p.m., and publicly opened by them at their office at that time for furnishing the County with One (1) Internal Combustion Land Dredge equipped with not more than three-quarter cubic yards capacity bucket, operated by at least fifty horse power. Internal Combustion Engine. The machinery must be so designed as to dig new ditches and also to clean out those already dug.

Bidders will be required to submit with their bids specifications in the minutest detail of the machinery they propose to furnish, giving full weight of machine, length of boom, turning radius, compression per square inch on Caterpillar Tractor, and the total load on hoisting cable at different elevations of the boom, with guarantee of cost of operation, etc., and must also state at what place similar machinery to that bid on is in operation.

Proposals must be accompanied by a certified check, money deposit or bidder's liability bond, payable to the Commissioners of Chatham County, in an amount equal to 5 per cent of the amount of the total bid, to insure the successful contractor delivering the machinery bid on and at the time he agreed to deliver.

TIME OF PAYMENT: The successful bidder will be paid on the 15th of the following month after delivery and acceptance of the machinery by the County Commissioners, by a warrant on the County Treasurer to be paid when in funds. Said warrant when presented to and stamped by the County Treasurer will bear interest at the rate of 7 per cent from the time of said presentation and stamping until paid.

The right is reserved to reject any or all bids and to waive all formalities.

COMMISSIONERS OF CHATHAM
COUNTY AND EX-OFFICIO JUDGES,
G. REUBEN BUTLER,
Clerk. (L. S.)

Bids: Feb. 5.

Sewers

Baton Rouge, La.

Sealed bids will be received by the Commission Council of Baton Rouge, La., at the City Hall, until 11:00 A.M., Feb. 5th, 1924, for constructing certain Sanitary Sewers and appurtenances in the City of Baton Rouge.

Approximate Quantities:
2,190 linft. 10 inch V. C. Pipe.
2,560 linft. 24 inch V. C. Pipe.
520 linft. 36 inch Cast Iron Pipe through levee.

17 Manholes.
Plans and specifications on file in the office of the Consulting Engineer, City Hall, Baton Rouge. Copies may be had upon payment of \$7.50, which will not be returned.

A certified check, or bidder's bond, for \$7,000.00, payable to the Commissioner of Finance, Baton Rouge, must accompany any bid. The right is reserved to reject any or all bids.

J. W. BILLINGSLEY,
Consulting Engineer.

Bids: Jan. 14.

Filtration Plant

North East, Pa.

Sealed proposals will be received up to eight o'clock p.m. Monday, January 14, 1924, at the Council Rooms of the Borough of North East, Pa., for the construction of a rapid sand filtration plant, complete, consisting of two units of a capacity of 600,000 gallons daily. Plans and specifications may be seen at the office of the Borough Engineer or of the Borough Secretary. A deposit of \$10.00 will be required for each set of plans given out to be refunded when contract is awarded and plans returned. All bids must be accompanied by a certified check for 5 per cent of the amount of bid and the right to reject any or all bids is reserved.

J. N. LEET,
Secretary.

OFFICIAL PROPOSALS

Bids: Jan. 17.

Double-Deck Bridge and Approach

New Orleans, La.

Sealed proposals will be received by the Board of Commissioners of the Port of New Orleans, at their office, Suite 200, New Court Building, until 3:00 P.M., Thursday, January 17, 1924, and then publicly opened for contracts in connection with the construction of a double-deck bridge and approach span, containing about 213 tons of structural steel, operating machinery and trim, for the ferry landing at the foot of Canal Street, New Orleans, La., as follows: Requirement E. D. 14393—Under one contract.

Furnishing structural steel for ferry bridge with or without erection of bridge, of machinery and of trim.

Requirement E. D. 14394—Under one contract.

Erection of ferry bridge, of machinery and of trim.

Requirement E. D. 14395—Under one contract.

Furnishing ferry bridge machinery. A deposit of \$1,000 in cash or certified check is required with the proposal to cover the first requisition and \$400 in cash or certified check with each of the other proposals.

A bond to the amount of fifty per cent (50%) of the sum bid will be required with each notarial contract signed. Specifications and proposal forms are on file in the office of the Supervisor of Purchases, at No. 1 Canal Street, New Orleans, Louisiana. Complete sets for each proposal will be furnished to prospective bidders on deposit of \$10 for each set, which will be refunded to depositors who submit proposals or return sets in good condition.

The right is reserved to reject any or all bids and to waive informalities.

J. H. WALSH,
General Manager.

Bids: Jan. 30.

42 in.—48 in. and 60 in.**Intercepting Sewers, Sewage Pumps, and Sewage Disposal Plant Improvements**

Fostoria, Ohio.

December 24th, 1923.
Sealed proposals for the construction of 42", 48" and 60" Intercepting Sewers and Pumping Machinery, Superstructures, Grit Chamber, Sludge Beds, and other improvements to the Sewage Disposal Plant, will be received by the City of Fostoria, Ohio, until 2 o'clock p.m., Eastern Standard Time, on the 30th day of January, 1924, and will then be publicly opened and read.

Official Proposal Blanks, Instructions to Bidders, Specifications, Plans of Construction and Bond may be seen at the office of the Director of Public Service, Fostoria, Ohio, or one (1) copy of plans and specifications may be obtained by bona fide bidders upon application to The J. N. Chester Engineers, Union Bank Building, Pittsburgh, Pa., or to the City of Fostoria, Ohio, and deposit of Twenty-five Dollars (\$25.00). An amount will be refunded to bidders on receipt of a bona fide bid, or upon the return within thirty (30) days after receipt of bids, of both plans and specifications, in good order.

The right is reserved to reject any or all bids.

JAMES MANECKS,
Director of Public Service.

Pittsburgh, Pa.

Bids: Jan. 11.

Viaduct and Retaining Wall

Seattle, Wash.

Sealed proposals will be received by The Seattle Board of Public Works up to 10 o'clock a.m., January 11th, 1924, for the construction of a concrete viaduct and retaining wall on West Spokane Street. Approximately 2400 cubic yards excavation, 4600 cubic yards concrete and 650,000 pounds reinforcing steel will be used with all necessary drainage and lighting.

Plans and specifications may be obtained of the City Engineer upon the payment of \$10, which will be refunded if the plans are returned in good condition.

J. D. BLACKWELL, City Engineer.

OFFICIAL PROPOSALS

Bids: Jan. 24.

Storm Drainage

Baton Rouge, La.

Sealed bids will be received by the Commission Council of Baton Rouge, La., at the City Hall, until 11:00 A.M., Jan. 24, 1924, for constructing certain storm drains in the City of Baton Rouge. The work will be let in three contracts, the Goose Hollow, Saint Philip, and Roseland Terrace Canals.

Combined Approximate Quantities:
4,250 cu yds. Class "A" Concrete.
384,000 lbs. Reinforcing Steel.
650 linft. Pipe.
16 Manholes.

Plans and specifications are on file in the office of the Consulting Engineer, City Hall, Baton Rouge, La. Copies may be had upon payment of ten dollars, which will not be returned.

A certified check, or bidder's bond, for five thousand dollars, payable to the Commissioner of Finance, City of Baton Rouge, must accompany each bid. The right is reserved to reject any and all bids.

J. W. BILLINGSLEY,
Consulting Engineer.

Bids: Jan. 10.

Water Main

Norfolk, Va.

Sealed proposals for relaying a 16-inch water main will be received at the office of the Director of Public Works, Norfolk, Virginia, until 12 o'clock noon, January 10, 1924, at which time and place they will be publicly opened.

The work includes taking up 22,000 feet of a present 16-inch main, hauling to the new location, and relaying same, together with necessary valves, hydrants, fittings, and cross-connections to small existing mains.

Plans, specifications, form of proposal, contract and bond may be obtained at the above office upon deposit of \$10.00, which will be refunded when plans and forms are returned.

A certified check on a Norfolk or other acceptable bank in the sum of Five Hundred (\$500.00) must accompany each bid. The right to reject any or all bids is reserved.

WALTER H. TAYLOR, 3RD,
Director of Public Works.

U. S. GOVERNMENT

U. S. ENGINEER OFFICE, Milwaukee, Wis. Sealed proposals will be received here until 3 p.m., Jan. 16, 1924, and then opened, for constructing steel dump scows and barge. Further information on application.

U. S. ENGINEER OFFICE, 260 Old Land Office Building, Washington, D. C. Sealed proposals will be received here until 12 M. January 15, 1924, and then opened, for the construction of the Filtration Plant and Pumping Station substructures for the District of Columbia water supply project. Further information on application.

U. S. ENGINEER OFFICE, P. O. Box 72, Louisville, Ky. Sealed proposals will be received here until 2 p.m., central time, Jan. 3, 1924, and then opened, for furnishing, delivering and erecting gates for Lock No. 45, Ohio River. Further information on application.

U. S. ENGINEER OFFICE, P. O. Box 72, Louisville, Ky. Sealed proposals will be received here until 2 p.m., central time, December 29, 1923, and then opened, for furnishing and delivering Metal Work for Dams Nos. 44 and 45 on Ohio River. Further information on application.

U. S. ENGINEER OFFICE, Cincinnati, Ohio. Sealed proposals for furnishing, delivering and erecting gates for Lock No. 34, Ohio River, will be received here until 11 a.m. January 19, 1924, and then opened. Information on application.

TREASURY DEPARTMENT, Office of the Supervising Architect, Washington, D. C., Dec. 20, 1923. Sealed proposals will be received in this office at 3 p.m., Jan. 21, 1924, for the construction, including mechanical equipment of a one story brick and tile non-fireproof Post Office building, approximately 60 x 60 feet in size at State College, Pa. Drawings and specifications may be obtained from the Custodian of the site at State College, Pa., or at this office in the discretion of the Supervising Architect, Jas. A. Wetmore, Acting Supervising Architect.

POSITIONS VACANT

AN experienced structural steel detailer wanted to do detailing and estimating. Location west of Mississippi River. P-254, Engineering News-Record, Old Colony Bldg., Chicago, Ill.

DRAFTSMEN and checkers, experienced in making shop drawings for structural steel work. Good opportunity for competent men. Apply Whitehead & Kaes Co., Detroit, Mich.

EXPERIENCED architectural and structural designer and estimator. Only technical graduates, thoroughly familiar with building codes need apply. State age, availability and salary. P-272, Eng. News-Record, Leader-News Bldg., Cleveland, Ohio.

ESTABLISHED construction company doing general building construction. Requires the services of an experienced estimator. State experience and salary expected in first letter. Communications confidential. Address P-176, Eng. News-Record, Real Estate Trust Bldg., Phila., Pa.

LEVELERS and rodmen for work on subway construction, New York City; entrance salary \$1,501 per annum, with opportunities for advancement; open to graduates in civil engineering or those with at least one year's satisfactory practical experience; citizens only; applying full information as to education and experience to Chief Clerk, Transit Commission, 49 Lafayette Street, New York City.

PUMP draftsman: Large mid-west manufacturer has opportunity for man familiar with centrifugal, steam and power pumps. Must be good detailer and thoroughly familiar with material lists. Good opportunity for young, energetic pump man. Location Michigan. P-251, Engineering News-Record, Leader-News Bldg., Cleveland, Ohio.

SEVERAL experienced bridge designers for highway work, wanted; must be good draftsmen. Give complete statement of education and experience, age and nationality. Submit sample of drafting. State salary. P-229, Engineering News-Record, Old Colony Bldg., Chicago, Ill.

STRUCTURAL engineers wanted for designing structural steel factory and mill buildings; also for designing reinforced concrete buildings; state experience in full detail and salary expected. P-245, Engineering News-Record, Leader-News Bldg., Cleveland, Ohio.

STRUCTURAL engineer, experienced in truss, general steel, design and drafting; give full particulars as to training previous positions age and salary expected. Asbury Bridge & Iron Works, Asbury Park, N. J.

STRUCTURAL engineer wanted, experienced in estimating and detailing, one with sales experience preferred. State experience, also salary expected in first letter. Southern Ohio territory. P-275, Eng. News-Record, Leader-News Bldg., Cleveland, Ohio.

POSITIONS VACANT

STRUCTURAL steel and railroad bridge draftsman wanted. State age, nationality, education, experience in full, salary expected and date you can report for work. Address P. G. Lang, Jr., Engineer of Bridges, Baltimore, and Ohio Railroad Company, Baltimore, Md.

SUPERINTENDENT to take charge of a sand and gravel dredging plant. Must understand the operation of floating derricks, having clam-shell buckets and hoisting sand and gravel out of beach. Must be familiar with the construction and operation of a screening plant, and the loading of scows. Location, forty miles from New York on Long Island. State age, experience and salary expected. P-186, Eng. News-Record, 10th Ave. at 36th St., New York.

WANTED (at once) structural draftsman. Only first-class men need apply. Apply Bethlehem Construction Company, Bethlehem Trust Bldg., Bethlehem, Pa.

WANTED: The Blaw-Knox Company has an opening for a young civil engineer interested in being trained for sales work. This is a good opportunity. Construction experience necessary, particularly in highway and concrete construction. Sales experience desirable but not essential. Write your story completely, with references in first letter, to Blaw-Knox Company, attention Sales Manager, P. O. Box 915, Pittsburgh, Pa.

WANTED, writer in civil engineering subjects; must be a college graduate with experience in railroad surveying and construction; position requires residence in Eastern city of 150,000. State education and experience, also initial salary expected in first letter. New York or Philadelphia interview. P-248, Engineering News-Record, 10th Ave. at 36th St., New York.

WE need a Surveyor who is experienced in the relocation of city and country property lines from descriptions by metes and bounds and who not only can keep, but is in the habit of keeping, full and complete notes of all he does. He need not be an engineer, though training as an engineer would not disqualify. We are not advertising for students. We want

POSITIONS VACANT

someone who can deliver the goods. Please do not reply to this ad unless you can fill the bill and are dependable, accurate, sound in mind and limb, and intend to stick. If you do answer, state age, education, experience, least salary considered, and date available. Box 796, Asheville, N. C.

WE require the services of an engineer-surveyor who is familiar with the following branches of work: relocation of property corners from descriptions by metes and bounds; stadia, road and sewer location and construction; topography, drafting, etc. Judgment in the first named branch is an important item. Please do not answer this ad unless you can fill the bill and are accurate, dependable, trustworthy and intend to stick. We do not want a rolling stone, as this will be a permanent job for the right man. If you do answer, state age, education, experience, least salary considered and date available. Brown & Gibbs, Asheville, N. C.

EMPLOYMENT SERVICE

SALARIED men seeking tentative offers of new connections, are invited to communicate confidentially with the undersigned, who will negotiate overtures without regard to present connections. A professional, ethical service, restricted to high grade positions, established 1910. Our "Refund Contract" guarantees refund of retaining fee to the client named therein, if service is not satisfactorily rendered and refund be requested within three months from date of mailing. Send name and address only for particulars. R. W. Bixby, Inc., 701 Lockwood Building, Buffalo, New York.

EXECUTIVES, engineers and other qualified men whose salary requirements are over \$2,500 per year, find our confidential direct service to specific employers extremely satisfactory. An inquiry entails no obligation. The National Business Bureau, Inc., 11 H. Harrison, President, Association Building, Chicago.

EMPLOYMENT AGENCIES

GENERAL ENGINEERING AGENCY. Monongahela Bank Building, Pittsburgh, Pa. Supply employers everywhere, freely, prepared proposals available plant managers, superintendents, chief engineers, designers, draftsmen, transmitters, office clerks, power engineers, electricians, master mechanics for every purpose. Individuals or groups. General registration, no restriction. Fees. Advise. Send men to Canada, Mexico, Central and South America.

NATIONAL CLERICAL BUREAU—Wisconsin's only technical agency offers special opportunity for our men to locate in Milwaukee and vicinity where diversified industries assure both opportunity for advancement and steady employment. No advance fee. Loan & Trust Building, Milwaukee, Wis.

WANTED—Teachers engineering subjects. Draftsmen, mechanical, structural, architectural and civil engineering work. Recent graduates for various engineering opportunities. Cleveland Engineering Agency, 308 Bldg., Cleveland, Ohio.

POSITIONS WANTED

Civil Engineers

CIVIL engineer, age 31, ten years' experience, highway location and construction, railroad location, construction, tunnel driving, industrial construction surveys, reports, estimating. Desires permanent position with chance of advancement through meritorious service. At present employed as resident engineer but available on short notice; location immediate. PW-214, Engineering News-Record, Old Colony Bldg., Chicago, Ill.

CIVIL engineer, 20 years' experience, Mexico and West Indies. Railroads, surveys and construction wharves and harbor improvements, highways, streets and sewers. Excellent record as sales engineer. Speaks and writes Spanish fluently. Available on short notice. PW-279, Eng. News-Record, 10th Ave. at 36th St., New York.

CIVIL and mining engineer, perfect knowledge of Spanish and Spanish American countries, desires representation of manufacturing, industrial or engineering firm in Chile, Peru, Argentina and Bolivia. PW-269, Eng. News-Record, 10th Ave. at 36th St., New York.

WILSON COURSES (By Mail)

"Engineer Makers" is what one enthusiastic student calls these courses; another student asks, "Isn't there some way of letting more draftsmen know about your courses?" "Thousands of good men are looking for just such practice work as you give in these courses, and they don't know where to find it."

We want to reach every technical graduate who needs Experience and every other man who has some knowledge of mathematics to start with; we have trained thousands in our 12 years of business and we invite communication with every man in the profession, regardless of age, who needs to modernize his methods, or get experience, or who is not satisfied with his present position through lack of confidence in his ability.

Reinforced Concrete Designing; Steel Designing;

Distributors
Wanted

For the most economical and efficient Adjustable Shore made in America. Eight years of proven worth. New factory being built to largely increase production. Excellent territory open. Handsome profits assured. Distributors will be backed by intensive advertising campaign.

Write immediately for details.

Address,

P. O. BOX 416, TOLEDO, OHIO

FABRICATED
STEEL PRODUCTS

We have just completed a large factory for the manufacture of all kinds of fabricated steel products and solicit your inquiry. We are prepared to render exceptional service on structural steel shapes and plates. Tell us what you need—we can make it. Representation desired in all territories.

The Building Products Co.

Toledo, Ohio

Construction Protection

The Quartermaster Auction at Boston, Jan. 17, offers Engineering Contractors a large amount of Waterproof Duck

The ever-present probability of unfavorable weather makes it inadvisable for the larger construction firms to allow their stocks of tarpaulin and other waterproof fabrics to run low. Here is an opportunity to replenish depleted stocks and lay up a large amount of waterproof fabric at a bargain price.

The Chemical Warfare Service has on hand at Edgewood Arsenal, Md., approximately 558,190 yds. of olive drab duck that was paraffined and waterproofed for gas mask fabric. It is to be offered for sale in the Quartermaster Auction to be held at the Army Supply Base, Boston, Mass., January 17. The material will be sold in lots of 5,000 yds. or more by sample, being available for inspection at point of storage daily, except Saturday and Sunday, between 10 A. M. and 2 P. M.

The Government feels that large structural engineering firms can profitably absorb quantities of this waterproof fabric and invites them to inspect the material. For all terms of sale and information, write for the catalog which is obtainable at the office of the Q. M. Supply Officer, 1st. Ave. and 59th. St., Brooklyn, N. Y., or the Commanding Officer, Army Supply Base, Boston, Mass.

The Government reserves the right to reject any or all bids.

At this same auction the Quartermaster Corps is offering 1,200,801 yds. of commercial duck of miscellaneous widths, weights and shades. Also a number of used motors and machine tools of well-known makes. This material is listed and fully described in the above-mentioned catalog.

WAR DEPARTMENT

STRUCTURAL STEEL BUILDINGS

At the Old Hickory Powder Plant, Old Hickory, Tennessee

4—Structural steel buildings, 85 ft. 6 in. wide, 184 feet long, and 75 ft. 6 in. high. Covered with corrugated iron. Heavy construction, as shown by picture. Designed for heavy loading on floors.

STRUCTURAL STEEL BUILDING

A building identical to these was recently dismantled and shipped to Detroit, Michigan, where it will be re-erected in almost the exact form of the original. *Good proof of the sales values at Old Hickory.*

USED EQUIPMENT

AND NEW, OFFERED FOR RE-SALE

Space for these advertisements is sold by the advertising inch—36 inches to a page. The price per inch is based on total space used—multiply ad space by number of insertions.

RATE PER INCH:
1 to 3 inches.....\$5.00 an inch
3 to 7 inches..... 4.50 an inch
8 to 14 inches..... 4.70 an inch

An inch is measured vertically on one column—three columns to a page. Any space may be used by the advertiser, inch in height by 1, 2, or 3 columns in width.

RATES FOR LARGER SPACES, OR SPACE ON A YEARLY BASIS, FURNISHED ON REQUEST.

"WE BUY, REBUILD, SELL or RENT" ANNOUNCEMENT!

In addition to our large stock of equipment listed on the lower part of this page, we have purchased the following equipment which was just released from a large sewer job being completed in Detroit. This equipment will not be loaded out to our Plants for several weeks, and we are now offering same for sale f.o.b. Detroit. Description as listed below:

BOILER

- 1—Ames Locomotive type 100 hp. Butt straced, complete with stack.
Also several small vertical boilers.

DUMP CARS

- 64—Western, 4-yd., 36-in. gauge.
27—K. & J., 4-yd., 36-in. gauge.
4—Drop bottom Concrete Cars, 36-in. ga.
12—Koppel 1½-yd., "V" shaped, cradle dump cars, 36-in. ga. All steel, spring draw bars and axles.

CRANE

- 1—15-ton Brown Hoist Locomotive Crane, 8-wheel MCB, standard 48-ft. boom also 1—65-ft. goose neck boom.

DREDGE

- 1—Hydraulic Dredge, Hull 32x8x110-ft., equipped with 12-in. Erie Pump, 250 hp. Ball Engine, tandem compound, and 300 hp. Scotch Marine Boiler, 3 Morrison Furnaces. This Dredge is complete with all miscellaneous equipment and is now located at Erie, Pennsylvania.

LOCOMOTIVES

- 1—Brooks, 18x24 standard gauge, 6-wheel switcher with tender. Weight on drives 45 tons.
2—Porters, 18-ton, 36-in. gauge, cyl. 10x16. Shop No. 5238 and No. 4012.
3—Vulcan, 18-ton, 36-in. gauge, cyl. 10x16. Shop No. 1012. No. 1577. No. 1575.
2—Porter, 14-ton, 36-in. gauge, cyl. 9x14. Shop No. 2873 and 3409.
2—Burton 2½-ton, 36-in. gauge, purchased new in 1921.

DRAGLINE

- 1—Class No. 20 Bucyrus Dragline Excavator, 2½-yd. Page Bucket, Steam, Shop No. 856, on skids and rollers. 85-ft. boom.

PUMPS

- Miscellaneous lot of piston pumps, consisting of Cameron & Prescott & Blake.
1—Pulsometer No. 3.
1—Pulsometer No. 7, 4-in. suction and 4-in. discharge.
1—Centrifugal, 8-in., direct connected to Westinghouse 9x8 engine.

STEAM SHOVEL AND CRANE

- 1—Erie type "B", traction wheels, high lift, ½-yd., also has ½-yd. sewer bucket and stick, also 30-ft. crane boom.
1—Bucyrus 70 C, Shop No. 1290, equipped with 2½-yd. dipper, new boiler.

All equipment listed below is in stock and may be inspected at one of our four Rebuilding Plants

CLAMSHELL BUCKETS

- 2—2-yd., 2 Owens, 1 OGS.
2—1½-yd. Williams heavy duty.
23—1-yd. Blaw Knox Standard, Lakewood, Owens.
31—¾-yd., Standard, Kessler, Hayward, Owens and Blaw Knox.
11—½-yd. All makes.

CONCRETE MIXERS

- 2—Ransome, No. 50-S, cap. 2-yd., on skids, without power.
60—Concrete Mixers, size 28S, cap. 1-yd., 21S, cap. ¾-yd.; 14S, cap. ½-yd. and 10S, cap. 1½-yd. With steam or electric power with side loaders or batch hoppers. Following makes: Marsh-Capron, Koehring, Milwaukee, Ransome, Smith, Smith-Chicago, Rex, Lakewood, Foster, Cady or Oshkosh.
42—7S, cap. 1 bag, with low charging platforms, with gasoline engines.

CARS

- 52—Koppel Flat Cars, 24-in. gauge, Spring Journal and draw bars, Frame 35x81x11 in. channels.
15—Lakewood Flat Cars, spring journals and spring draw bars, ball bearing

CATERPILLAR CRANE

- 1—Northwest Combination Crane and Dragline caterpillar, 40-ft. boom, 70 hp Gasoline Engine, ¾-yd. Page Bucket.
1—Brownhoist, combination Crane & Dragline, 40-ft. boom, ¾-yd. clam shell bucket, has ¾-yd. skimmer scoop attachment also equipped to handle 1-yd. Dragline bucket.

COMPRESSORS

- 1—Ingersoll-Rand, Steam cap. 960 cu. ft. per minute, 100 lb. pressure.
1—Sullivan, Class W-63, belt driven, cyl. 10x12.
1—Westinghouse, size 11x11x12, on skids.
1—Westinghouse, size 8x8x8, on skids.

ELECTRIC HOISTS AND DERRICKS FROM HOG LAND

Specifications of Electric Hoists

- 35—American late model hoists. These hoists have 2 drums with attached swinging gear, with 37-hp. Otis A.C. 440-v., 60-cy. 3-ph. electric motors—complete with controllers and resistance grids—can be changed to suit customer's current requirements if desired.

Can furnish counterweighted holding drums with these hoists when used for operating bucket.

Also several 55 and 75-hp., single and double drum hoists with A.C. motors

Specifications of Derricks

Large number of practically new American Mast, 11x11x80-ft., trussed.
Mast, 16x16x40 ft.
Legs, 11x11x32-ft.
Bull wheel, 16 ft.

For Single Line Work or Arranged for Bucket Operation

Will sell fittings only if desired. Also have large stock of lighter stiff leg derricks, several steel stiff-legs, 20 30 and 50 ton.

GUY DERRICKS

- 9—Wood Guy Derrick, bucket operating or hook line, masts 60 to 90 ft., booms 50 to 80 ft., with "American" fittings.

STEAM HOISTS

- 10—Three-Drum Hoists, with or without boilers. Sizes, 8x12, 9x10, 8½x10, and 7x10, with separate swinglers for derrick work. All makes.
26—Two-Drum Hoists, with or without boilers. Sizes, 10x12, 9x10, 8½x10, 7x10, 6½x10, 6x8, and 5x8. Can be equipped with holding drum for bucket work. Several special Cableway Excavator or Drag Scraper Hoists, all makes.
2—8½x10 American, D.C., D.D., with swinglers.
1—7x10 National Single drum with boiler.

LOCOMOTIVES

- 2—3 ton Plymouth, 24-in. gauge gasoline.
1—7 ton Davenport, 24-in. gauge, steam.
1—4 ton Whitecomb, 24-in. gauge gasoline.
1—6 ton Plymouth, 24-in. gauge, gasoline.

ROAD ROLLERS

- 1—10 ton Austin, 3-wheel, gasoline, single cylinder.
1—10-ton, 3-wheel, steam—2 Buffalo-Pitts 1 Kelly-Springfield, 1 Perrier, 1 Monarch.
1—3-ton Trapslet-Tandon, steam.
1—3-ton Erie Tandem, steam new.

STEAM SHOVELS

- 4—Keystone Excavators, 1—No. 3, 1—No. 4.
2—Type O Thew on traction wheels with ¾-yd. dipper.
1—Type A-1 Thew, traction wheels, ¾-yd. dipper.

CRANES

- 2—Biers Auto Cranes, on traction wheels, with 30 ft. boom, with ½ or ¾-yd. clam shell bucket, 1 steam, 1 gasoline.
1—15-ton, 8-wheel, O.S., 10-ft. boom.

The above is only a partial list of our equipment. Write for latest stock list

FOR SALE OR RENT

STEAM SHOVELS

- 1—Type B Erie Traction. Shop No. 321. 4-yd. dipper.
- 2—70C Bucyrus. Shop Nos. 1277, 1445, 1482, 1499, 1582, 1608 and 1998; 2½-yd. dippers.
- 3—70-ton Bucyrus. Shop Nos. 920, 977, and 1293. 3½-yd. dippers.
- 1—Model 60 Marion. Shop No. 2367. 2½-yd. dipper.
- 1—Model 80 Marion. Shop No. 876. 4-yd. dipper.

STEAM SHOVEL PARTS

- 1—1½-yd. Coal Loading Dipper for Marion 36 Steam Shovel.
- 2—Booms for 70-ton Bucyrus, length 29 ft.
- 1—Boom for 70C Bucyrus shovel, composite, length 40 ft.
- 1—Marion Dipper, 2½ cu. yd. capacity.
- 1—Bucyrus Dipper, 3 cu. yd. capacity.
- Jack Arms and Boom Engines for 70-ton Bucyrus Shovels.

DRAGLINE EXCAVATORS

- 1—Class 7 Bucyrus. Shop No. 798, mounted on skids and rollers, 42 ft. boom, 1-yd. bucket.
- 1—Class 14 Bucyrus. Shop No. 745, mounted on skids and rollers or tandem wheels, 60-ft. boom, 2-yd. Page bucket.
- 1—Class 14 Bucyrus. Shop No. 2140, mounted on caterpillars, 60-ft. boom, 2-yd. Page bucket.

LOCOMOTIVES

- 1—18 x 24 American, 6-wheeled switcher, Brooks No. 2318. Wt. 55 tons on drivers.
- 1—18x24 American, 6-wheeled Switcher, Brooks No. 1778. Wt. 50 tons on drivers.
- 1—16x24 Baldwin 6-wheeled Switcher, with tender. Shop No. 44887. New in 1917. Wt. 43 tons on drivers, 180 lbs. pressure.
- 1—16x24 Vulcan 4-wheeled Switcher with tender. Shop No. 1744. Wt. 40 tons, 180 lbs. steam pressure.

LOCOMOTIVES (Continued)

- 1—16x24 Baldwin 4-wheeled Switcher with tender. Shop No. 37643. Wt. 39 tons, 180 lbs. steam pressure.
- 1—16x24 Davenport 4-wheeled Switcher, with tender. Shop No. 900. Wt. 38 tons, 170 lbs. steam pressure.
- 1—17x24 Baldwin 4-wheeled Saddle Tank Locomotive. No. 15683. Wt. 47 tons.
- 1—16 x 22 C. M. & St. P. Ry. Class J-2, 4-wheeled switcher. Weight 32 tons.
- 1—Std. gauge 11x16 Davenport Dinkey. Shop No. 1163, new in 1912. Air brakes, automatic couplers. Wt. 20 tons.
- 1—Std. gauge 11x16 American 4-wheeled Saddle Tank Locomotive, Shop Nos. 46349 and 4721, built 1912. Wt. 21 tons. Steam brakes, automatic couplers.
- 1—Std. gauge, 11x16 Davenport Dinkey. Shop No. 1027, new in 1910. Steam brakes. Wt. 20 tons.
- 1—36-in. gauge, 10x16 Vulcan Dinkey. Shop No. 868. Wt. 18 tons.
- 1—Std. gauge, 7x12 Davenport Dinkies. Shop Nos. 1411 and 1524. Wt. 9 tons.
- 1—24-in. gauge, 7x12 Vulcan dinkey. Shop No. 2345. Wt. 9 tons.
- 1—24-in. gauge 6x10 Davenport side tank Dinkey. Shop No. 1307. Wt. 7 tons.
- 1—24-in. gauge 5x10 Shay geared. Lima No. 268. Wt. 12 tons.
- 1—24-in. gauge, 6-ton Plymouth. Type 2, No. 1077.

CRANES

- 1—30-ton Ohio Locomotive Crane. No. 3416, new in 1919. 55-ft. boom, 20-ft. extension, 1½-yd. clam shell bucket.
- 1—Halle Type Crane, built by Variety Iron & Steel Works. New in 1919; 48-ft. boom, 15-ton cap. at 18-ft. radius; 7-ft. 10½-in. gauge, 12-ft. wheelbase, self-propelling. Base of boom 17 ft. above track. Bucket-operating drums. Wt. 50 tons. Price, 25% of new.
- 1—10-ton Industrial Crane (Shop No. 1899). 4 wheeled, 40 ft. boom.
- 1—Crane boom, 33 ft. long, drum and necessary equipment for converting type B Erie shovel into crane.

DUMP CARS

- 38—20-yd. Western, all steel Air Dump Cars, 80,000 lb. capacity.
- 1—12-yd. Western Air Dump Cars, 19-ft. beds, steel sills, box girder doors.
- 1—16-yd. Western Air Dump Cars, steel sills, box girder doors.
- 8—12-yd. Western Hand Dump Cars, 19-ft. beds, steel sills, box girder doors, wood beds.
- 13—8-yd. Western, 36-in. gauge, double truck side Dump Cars; steel draw sills, wood beds.
- 4—4-yd. Continental, 36-in. Gauge Side Dump Cars, wood beds, steel draw sills.
- 9—12-yd. Western Air Dump Cars, 26-ft. beds.
- 4—4-yd. Western, 36-in. gauge, Wood Sill Dump Cars, truss rod doors.
- 2—4-yd. Continental, 36-in. gauge, wood draw sills, 4 pedestals, truss rod doors.
- 8—3½-yd. Peterli 36-in. gauge side dump cars, wood sills and wood beds.

SPREADER CARS

- 1—Std. gauge Jordan All Steel Spreader Car, 100,000 lb. capacity. Shop No. 317.
- 1—Std. gauge Western Spreader Car.
- 1—36-in. gauge Western Spreader Car.
- 1—36-in. gauge Oliver Spreader Car.

MISCELLANEOUS

- 1—7x10 D.C. D.D. Lidgerwood Hoist No. 15967. No boiler.
- 1—7x10 D.C. D.D. Lambert Hoist, with or without boiler.
- 3—1½-yd. Western Bottom Dump Wagons.
- 3—Locomotive Air Pumps, 1½-in. and 11-in. simple, 8½-in. and 9½-in. cross compound.
- 2—80-hp. horiz. Boilers, with fittings.
- 1—1½-yd. Page Dragline Bucket.
- 6—Mead-Morrison 1½-yd. Clam Shell Buckets.
- 3—1½-yd. O. & S. coal loading clam shell buckets.

Waterloo Catalogue No. 719

THE GEO. HAISS MFG. CO., INC.

1300 8th and Rider Ave. New York, N.Y.

Complete Power Plant

Purchased from U. S. Navy, Boston

NEW 25-TON BALDWIN 4 WHEEL, STANDARD GAUGE, GASOLINE LOCOMOTIVE

Heating Plant

1—72-in. x 19-ft., 6-in. Dillon, 125 lb., Mass. Std. HRT Boilers, with breeding, pipping, all regular fittings, feed water pumps and Cochran Feed Water Heater.
Also centrifugal pumps, tanks and piping to complete the circulating sys-

tem in connection with the hot water heating, serving 60,000 sq. ft.

1—High pressure and low pressure U-type Pittsburgh Company heating coils.

Power Equipment

- 2—1730-cu. ft. OCE Chicago, dir. coun. electric compressors, 3 ph., 60 cy., 2200-550-410-220 v.
- 3—130-cu. ft., 110-lb. brass tube Air Aftercoolers.
- 1—100-gal. Yeomans Sewerage Duplex Ejector Pump, 10-ft. head, 3-60-550 v.
- 2—35.6-gal. Morris Centrifugal Pumps, 50-ft. head, D.C. to 3-60-550 v. motors.
- 1—35.0-gal. DeLaval Centrifugal Pump, 90-ft. head, D.C. to 3-60-550 v. motor.
- 1—1800-gal. DeLaval Centrifugal Pump, 75-ft. head, D.C. to 3-60-550 v. motor.
- 1—1800-gal. DeLaval Cent. Pump, 75-ft. head, D.C. to DeLaval Turbine.

PIPING—Considerable quantity of iron and brass piping, including about 150 various types and sizes of valves, also pipe covering.

- 1—750-kw. Syn. G. E. Converter, 240-120-v. Panels, Transformers 3-60-13,800 or 6900 v.
- 1—60-kw. Syn. G. E. Converter, 240-120-v. Panels, Transformers 3-60-13,800 or 6900 v.
- 1—250-kw., 125-v. Deihl Generator, D.C. to Kerr Turbine.
- 6—250-kva., Pittsburgh single phase, 60 cy., Transformers, primary 13,200 v., secondary 2300 v.
- 3—200-kva., Packard, single phase, 60 cy., Transformers, primary 13,200 v., secondary 275 v.
- 15—Panels, switchboard equipment, all purposes.

PLANT OPERATED TWO YEARS, ALL EQUIPMENT INSTALLED IN DUPLICATE.

I SPECIALIZE IN COMPRESSORS

- 2588-ft. OC-2 Ingersoll, compound steam, 2 stage.
- 2570-ft. Laidlaw Feather Valve, compound steam, duplex air, 60 lb.

"DECO" Rebuilt Equipment

Davis Equipment Company

50 Church Street Tel. Cortland 2895 New York City

823 H. P. Stirling Water Tube Steam Boilers

From the Old Hickory Powder Plant, Old Hickory, Tennessee. Used less than ninety days, and in excellent condition. Inspection invited.

OFFERED AT MONEY SAVING PRICES

SPECIFICATIONS

Class M-40, each unit having 8226 sq. ft. heating surface, in accordance with following specifications and A.S.M.E. Code. The heating surface of each boiler consists of three steam and water drums and a mud drum, as follows:

3—Steam Drums 12-in. diameter, 17-ft. 1½-in. long, ¾-in. plate

DRUM CONSTRUCTION

All flanges for blow-off, feed, safety valve and water column connections made of wrought steel and riveted to the drums. The cylindrical portions of each drum made of a tube plate and a shell plate. Longitudinal seams double riveted, butt joint, circular seams, single riveted, lap joint.

TUBES

Tubes, 3¼ in. I.D., hot rolled, seamless steel, No. 10 gauge, for working pressure of 150 pounds to and including 22½ pounds. Spaced alternately wide and narrow to facilitate replacement.

VALVES AND FITTINGS

Each boiler supplied with the following valves and fittings:

- 1—1½ in. Safety Valves, nickel steel, set to blow at 200 pounds.
- 1—15 in. Ashcroft Steam Gauge with 12-in., 100 lb. dial.
- 1—Water column fitted with bronze mountings for glass water gauge with special shut-off device operated from the room floor to allow removal of glass under pressure. Three try cocks with lifting handles for operating from fire room floor, fitted with steam metal valves. Independent blow-off pipes from bottom of column and glass gauge, carried down the floor terminating in the ash pit, fitted with valves at height of hand.
- 1—3-in. Hancock Bronze Stop Valve and one 3-in. Hancock Bronze Check Valve for feed.
- 2—2½ in. Blow Off Valves and two Stop Cocks
- 2—2½ in. Bronze Stop Valves on steam dusting hose connection.

STOKER ENGINE

1—808-in. Buffalo Vertical Engine, single acting, Inched type, Class A, rated at 22 hp., 150 r.p.m., equipped with one 2½-in. Buffalo governor. Engine and accessories by Buffalo Forge Company

1—Mud Drum 18-in. diameter, 16 ft. 7½-in. long, 1-in. plate. Drums connected by 630 tubes 3¼-in. diameter, connections made by expanding wrought tubes into reamed tube seats. Spaces occupied by each boiler 18 ft. wide, 3½-in. deep, 29-ft. 9-in. high

FIXTURES

A full set of cleaning and ash doors and frames for side and rear walls, gilding access to all parts for exterior cleaning. A large circular door and frame for access to mud drum manifold. Necessary bunkways and the rods for securing all parts in position, and supports for hulle walls.

WORKING PRESSURE

The boilers were constructed for working pressure of 200 pounds per square inch. All drums were tested and made tight under hydrostatic pressure of 300 pounds. When erected complete the boilers were tested and made tight under hydrostatic pressure of 250 pounds.

ACCESSORIES

Accessories furnished in addition to those mentioned:

- 1—8 in. Foster Non-return Valve.
- 1—6 Element Vulcan Steam Blower complete with all pipe and valves.
- 1—Bulley Flow Meter, Type D 25, Class 58; rated for 25,000 pounds per minute, maximum flow 70,000 lbs. per hour.
- 1—Retort Westinghouse Double Pump Engineered Stoker, with lime shaft, sprockets, transmission gear, extension coal hopper, etc.

FAN AND TURBINE

1—Buffalo Turbo Compound Fan, Type T D 9½, double inlet, capacity 100,000 cu. ft. per minute at 6 in. water pressure and 970 r.p.m. Driven by 225 hp. horizontal multi-stage, non-condensing, Moore Turbine and reduction gear set, 1-ratio, 3000 r.p.m.—970 r.p.m. Throttle valve J in. Steam consumption at 150 hp.—31.6 pounds; at 225 hp.—33.2 pounds.

A Service You Will Appreciate

My business is more than merely buying and selling used cranes. It is knowing exactly what service cranes are capable of and how different types should be used. When you are in the market for a locomotive crane, I can help you select the one best suited for your needs—and probably save you money on your purchase.

Locomotive Cranes

- 1—Rebuilt Industrial, 20-25 ton cap, double drums, 50-ft. boom, outriggers, 8-wheel MCB. Like new. Guaranteed. Located Bay City, Mich.
- 1—23-ton McMyler, 8-wheel MCB, double drums, 45-ft. boom, with 7½ kw. Engberg Generator. Located Buffalo, N. Y.
- 1—20-ton cap. Brown Hoist, single drum, 40-ft. boom, 8-wheel MCB. Located Philadelphia, Pa.
- 1—20-ton cap. Industrial, 8-wheel MCB.

- double drums, 50-ft. boom, 1½ yd. clamshell bucket. Located La Salle, Ill.
- 1—25-ton cap. Model "E" Ohio, 8-wheel MCB, double drums, 50-ft. boom, Brand New. Located Bucyrus, Ohio.
- 1—30-ton cap. Model "F" Ohio, 8-wheel MCB, double drums, 50-ft. boom, Overhauled; like new. Located Hartford, Conn.
- 1—7½-ton cap. Osmond, double drums, 4-wheel, standard gage, 40-ft. boom. Located Kingston, N. Y.

A New Hool Book

Ready Hool and Kinne's Foundations, Abutments and Footings

413 pages, 6x9
bound in special
buckram, fully il-
lustrated, \$3.00
net, postpaid.

Editors-in-Chief: GEORGE A. HOOL and W. S. KINNE
Assisted by seventeen specialists

This new Hool Book—the work of nineteen engineering specialists—presents the whole problem of foundation and substructure work clearly, thoroughly and authoritatively.

The details of design—equipment, methods and cost of construction—the entire how and why of the subject—make up the invaluable contents of this practical work. Much of the material has never before been available in book form.

Other Hool and Kinne Books

Structural Members and Connections, \$6.00
Movable and Long-Span Bridges, \$5.00
Stresses in Framed Structures, \$5.00

Exclusive Features Nos. 16 & 17

The front sprocket The pressed steel radius rod

WHEN the International Motor Company developed a drop-forged front sprocket, case-hardened its teeth and used it in conjunction with hardened chain rollers, the present-day efficient Mack chain drive was made possible. This drive not only performs efficiently and economically under normal going but has no equal when operating under adverse load and road conditions.

The Mack pressed steel radius rod is made in channel section and is lighter for a given strength and more flexible than common cast rods. This construction assures unvarying chain centers under all driving conditions. The large ball joint at its front end permits a single connection that adjusts itself to chassis movements. It is held by a socket that forms part of a drop-forging bolted to the chassis frame independent of the jackshaft.

INTERNATIONAL MOTOR COMPANY
25 Broadway New York City

Branches owned by this company operate under the titles of: "MACK MOTOR TRUCK COMPANY" and "MACK INTERNATIONAL MOTOR TRUCK CORPORATION."

The 27 exclusive features listed are the result of 23 years of specializing in motor transportation. Each one has played an important part in building the reputation which Mack Trucks have established wherever motor trucks are known.

THE COMPLETE LIST

- 1—Crankshaft
- 2—Cylinder Treatment
- 3—Engine Support
- 4—Case-Hardened Timing Gears
- 5—Water-Cooled Oil Reservoir
- 6—Double-Screen Oiling System

Put Rigid Rail Tracks on Your Fordson

To Meet All Conditions!

Rigid Rail Tracks on your Fordson assure power a-plenty for any condition. No roads too muddy, no sand too deep—and no slipping. Twice the pull with the same amount of fuel. Turns easily in short space. Upkeep small. Insures greater profits for the road builder.

Our "One Man Grader" cuts your grading gang to "One Man" and your cost to 25 per cent.

One man and the H. P. One Man Grader attached to a Fordson will do as much work as two graders, six teams and four men.

Portland Cement Stucco Is Quality Stucco

The high recognition accorded Portland Cement Stucco by the architectural and engineering professions is due primarily to its dependability. The reason for this dependability is the fact that its most important ingredient—Portland Cement—is *standardized*.

Not only has Portland Cement Stucco superior strength and durability; applied in accordance with the most advanced specifications, it assures structures of distinction and beauty.

Our new booklet, "Portland Cement Stucco," gives all details of good practice. From these you can write your own specifications.

This booklet is yours for the asking. It is a practical "how-to-do-it" book for the superintendent and foreman, as well as a reference book for the architect, engineer and contractor. Here are a few of the things it contains:

- Typical Construction Details with Sketches.
- Varieties of Surface Finish and How Obtained.
- Notes on Coloring Pigments.
- Proportioning Mixtures.
- Use of Hydrated Lime.
- Back Plastered Work.

Send today for "Portland Cement Stucco." It is a booklet you will want to keep. Address our nearest District Office.

Acid, the destroyer, won't affect this pipe

It is an admitted fact that by the action of decomposition and bacteria, sewage will generate great quantities of Hydrogen Sulphide Gas. This in turn rapidly forms Sulphuric acid in the presence of air and water which becomes a menace to the walls of the sewer itself.

You can transport Sulphuric Acid in glass bottles without the slightest damage to the glass! So what's the answer?

Line your sewers with glass!

And this is exactly what Vitrified Salt Glazed Clay Sewer Pipe does. It brings the engineer a sanitary Glazed Sewer Pipe impervious to the actions of chemicals, which when properly laid will last a lifetime, insuring a healthy community, freedom from constant and expensive repairs and the danger of total breakdown, facts in which every city engineer should be interested.

Protect yourself and your community by specifying Vitrified Salt Glazed Clay Pipe, the Sanitary Sewer Pipe.

HARDESTY

Irrigation Supplies

*This mark is
Your Guarantee*

The Ditch Rider

Will tell you that when the name Hardesty is on a headgate—there you will find efficient water control, at a minimum of cost. That is the reason engineers the world over specify Hardesty Products.

Here is a line of gates so made that the surfaces on which water tightness depend are machined and in which unnecessary refinements are eliminated. Think what it means to be able to select, for immediate delivery, standard irrigation equipment scientifically and uniformly designed.

Hardesty Gates are
"The Standard of Excellence."

The R. Hardesty Mfg. Co.

31st and Blake Streets,
Denver, Colorado

Woods Cross, Utah Pocatello, Idaho Missoula, Mont.

15,000,000 Cubic Yards of Reinforced Slag Concrete

are in use in United States today—in bridges, buildings, sewers, pavements, roads—in fact, everywhere that concrete can be used. The extensive use of Blast Furnace Slag is the best indication of its great success as a concrete aggregate.

There is no type of architectural construction involving the use of concrete which is not represented by examples constructed by the use of Blast Furnace Slag as the aggregate.

Use More Concrete

462 Broad Street, Newark, N. J.

Now, after fifteen years of general use—

it is time to make some general observations.

Men who have inspected culverts—men who have actually climbed out of their cars hundreds of times and delved into the condition of highway substructures—make the following report:

No culverts of any material prove so dependable—give such certainty of service as Armco Culverts.

No culvert material can honestly claim greater permanence than Armco Culverts.

No culverts seem less affected by time and service than Armco Culverts.

Perhaps the culverts in your district will bear out the truth of these observations. When making your inspection be sure the corrugated culverts on which you pass judgment are genuine Armco Culverts—not culverts “just as good” as Armco.

This Little Dot

If this triangle were a sheet of ARMCO Ingot Iron, this little dot would represent all impurities. If it were the least bit larger by the addition of any other material, the iron could not bear the ARMCO Trade-mark. There is less than 1 part impurities to every 625 parts of pure ferrite—less than 1 ounce to every 39 pounds of pure iron.

There is a manufacturer in almost every state and in Canada, making Culverts, Flumes, Siphons, Tanks, Roofing, etc., of genuine, rust-resisting Armco Ingot Iron. Write for full information and nearest shipping point on products in which you are interested.

**Buyers Know the Uniformity
and Dependability of**

LONG-BELL LUMBER and TIMBER

For years Long-Bell lumber and timber have been meeting the exacting demands of buyers. Production has steadily increased; manufacturing methods and equipment have been bettered at every opportunity. Nothing is left undone to safeguard the production of uniform, dependable lumber and timber—with the added assurance of *shipments when promised.*

Why the Long-Bell Product Is Dependable

- | | |
|---|---|
| 1—It comes from virgin forests. | 9—Uniform seasoning. |
| 2—Each log is cut and manufactured for the purpose to which it is best adapted. | 10—Lower grades receive the same care and attention as upper grades. |
| 3—Milled in our own mills, all operating with modern machinery under a uniform process and efficient supervision. | 11—Correctly piled and stored—carefully shipped. |
| 4—Unsurpassed accuracy and thoroughness at every step of manufacture. | 12—Minimum of carpenter labor—planing, sawing and sorting—necessary to put into construction. |
| 5—Surfaced (planed smooth) four sides. | 13—Minimum of waste, due to uniform quality. |
| 6—Unusual care in trimming. | 14—The product of a lumber company 47 years in the business. |
| 7—Full length—uniform in width and thickness. | 15—Long-Bell Lumber can be identified by the Long-Bell trade-mark on the piece. |
| 8—Uniformity of grading. | |

THE LOGICAL WAY TO JUDGE PAINT

The correct way to judge value in paint is to base your decision on the record of that paint in service over a long period of years. No other measure of value will do.

The wide use of SUPERIOR GRAPHITE PAINT in every line of industry—its durability under every phase of exposure and operating conditions—its low per year cost—are vital factors in its remarkable service records that have won for SUPERIOR GRAPHITE PAINT its enviable position of leader in the field of metal protective coatings.

Whenever you think of metal protection, think of SUPERIOR GRAPHITE PAINT. Its use is definite assurance of service and satisfaction.

DETROIT GRAPHITE COMPANY
556 Twelfth Street Detroit, U. S. A.

New York: 21 Park Row

A Service Tested Wire Rope

The use of HERCULES (Red-Strand) Wire Rope on heavy duty equipment is not an experiment, for its many years of actual service have demonstrated that it is a safe and economical rope for such conditions. Its one red strand is our guarantee of constant quality.

McKiernan-Terry Hammers building for the Brooklyn Edison Co.

11 Cofferdams enclosed with 15-in. steel sheet piling in 70-ft. lengths driven with 9-B Pile Hammers. Two of the five hammers used on this operation were subsequently employed for driving 14-in. timber piles 15 to 25 ft. long within the cofferdams, to grade, which submerged the hammers 30 to 40 ft. below water level.

Driving above or below water is done with equal success by the B-line of pile hammers; they are as efficient one way as the other.

THOMAS

Steam and Electric Building Hoists

This type of double drum Thomas building Hoist is aiding many contractors to speed up the job and make money. Like all Thomas Hoists, it is a thoroughly well-built and dependable unit, equipped with patented band friction and automatic irreversible motor brake, turned and brushed drums, cut gears, variable speed motor, etc. Friction driven boom swinger can be added at any time.

These hoists are built to give the dependable service which successful contracting necessarily requires. Write for Bulletin 15.

Cranes—Shovels—Buckets

"With our 3-nd. WILLIAMS' 'Special Dredging' Bucket, we have excavated as high as 174,000 cu. yds. per month," writes F. P. Gillen, Pres. & Gen. Mgr. of the Edw. Gillen Dock, Dredge & Constr. Co., Beardstown, Ill.

For any kind of hard digging—

get the bucket that gives you biggest output

The large output that you get with the WILLIAMS Special Dredging Bucket comes from its speedy action, and the power that the WILLIAMS tandem sheave closing arm gives for a big fast bit into tough materials.

Under water, a bucket runs into large boulders, imbedded timbers, etc., that finish an ordinary bucket in short time. But — you are protected by the WILLIAMS guarantee—"all parts guaranteed against breakage, as long as the bucket is used for the work intended."

We have a 60-page catalog that shows working photos and full descriptions of every bucket in the complete WILLIAMS line. Write for Catalog N-60.

GAMON METER COMPANY

Main Office and Works:
NEWARK, NEW JERSEY

Number ten of a series of advertisements explaining the use of Simplex Venturi Tube Meter and its practical application

THE SIMPLEX Venturi Tube Meter

is admirably adapted for Filter Plants

Cut shows standard Simplex Meter Register connected to a Venturi tube which is inserted in the pipe line.

The present practice is to check the performance at all times of the entire plant, or any of its units, by measuring the raw water delivered to the sedimentation basin, the daily amount handled by the filters, the amount of wash water required and the gallons per day consumed by the distribution system. The Simplex meter is an ideal device to determine these data and for regulating the amount of chemical solutions that must be added to the water in proportion to the rate of flow.

Repeat orders from many engineers and water works managers are the testimonials of the faith placed in Simplex Devices for their filtration plant.

“IN the elder days of art
Builders wrought with greatest care
Each minute and unseen part
For the Gods see everywhere.”

—LONGFELLOW (*The Builders*)

TODAY that same spirit dominates the automatic machinery in the Neptune Meter Plant—for everywhere the eyes of the waterworks field are upon Trident Meters. That Trident Meters are “wrought with greatest care” is one reason why over 2,500,000 are in use today, and over 200,000 were made and sold during 1922.

Time-Tested Quality

The design and construction of Jenkins Valves represent the accumulated knowledge gained from 59 years of valve manufacturing experience.

They have proved their quality by years of unflinching valve service.

This time-tested quality is symbolized and protected by the Jenkins signature and "diamond," cast on the body. Look for these marks, they assure you of durability and dependability in valves.

Valves in bronze, iron and steel for all requirements. At supply houses everywhere.

Single and Two-Stage, open impeller pumps ¾ in. to 24 in. discharge openings. Double suction pumps, 1½ in. to 72 in. Multistage pumps all capacities. Deep well turbines and Power Heads. Special Mine-Sinker Pumps.

AURORA PUMP & MFG. CO.,
Loucks St., Aurora, Ill.

Worthington Diesel Engines

A type for every service

Three typical Worthington Diesel engines are shown here, but there are others bearing the same name, making a complete line from which to choose the exact type for a particular situation. The line of Worthington Diesels includes horizontal and vertical, two and four-cycle, solid-injection and air injection, stationary and marine types.

Vertical four-cycle Diesel engine with guided piston and a distinctive frame design having exceptional accessibility and unusual strength. (The latest development in air injection Diesel engine design.)

A vertical, two-cycle, solid-injection, Diesel of greatly simplified design.

The Worthington-Snow horizontal four-cycle Diesel engine, a massive, sturdy engine for heavy duty.

WATER MAINS

In connection with our work as waterworks general contractors, we are prepared to furnish and lay cast iron and riveted steel pipe in all standard sizes. Recently, at Wheeling, W. Va., we began work on a contract involving laying approximately nine miles of large diameter cast iron and steel pipe. A permanent field organization handles all of our waterworks undertakings. Its members are thoroughly experienced and conversant with the best engineering practices. Pittsburgh-Des Moines service will meet every test.

In addition we fabricate and erect Elevated Water Towers, Stand Pipes, Oil Storage Tanks, Buildings, Bridges, etc.

The estimator's source books of actual costs—

Thousands of pages of detailed, actual costs, carefully analyzed and itemized—on every conceivable kind of civil engineering project. This library shows and explains the methods used on actual jobs and tells you how much every step of the work cost. Special attention is given to construction costs. The books will be of interest to contractors, architects, structural engineers, highway engineers, water-works engineers, sanitary engineers and hydraulic engineers.

They help you take the guess out of esti- mating.

They explain the value of using accurate cost data—how to make a rapid and preliminary estimate of cost—give a typical complete cost estimate as an example—discuss factors a contractor should consider in making estimates—give the authors' formulas for commodity price levels and wage levels. And in addition—several thousand pages of actual, itemized costs of actual jobs.

*Small
monthly
payments*

*No money
down*

*Sent on
approval*

Examine Gillette and Dana's COST DATA LIBRARY

for ten days FREE

Three volumes, handbook size

Only \$3.00 in ten days and \$5.00 monthly for three months

The authors of these books have specialized on cost data for more than 25 years. During that time they have conducted appraisals aggregating more than \$650,000,000. Their experience and wide costs information have made these three books the accepted authorities on civil engineering cost data.

This Cost Data Library will save you money and trouble on every estimating job. It will enable you to check estimates with the assurance of definite data.

They cost only 18 cents a day for a short period

Just fill in and mail the coupon. This will bring these three great cost data books to you for ten days' free examination. You can look through the books yourself, you can satisfy yourself of their value to you, you can use them in checking up some estimate you are now working on. If you find that the books are dollar-savers, send us \$3.00 in ten days and \$5.00 monthly for three months. If you do not wish to purchase the books, you may return them, postpaid, in ten days, without question and without red tape.

FREE EXAMINATION COUPON

McGraw-Hill Book Company, Inc.,
370 Seventh Ave., New York.

You may send me the Cost Data Library for my inspection. If the books prove satisfactory, I will send \$3.00 in 10 days and \$5.00 per month until I have paid the price of the books, \$18.00. If the books are not what I want, I agree to return them postpaid within 10 days of receipt.

Bargains in Used Blue Printing Machines

We have on hand a number of used blue print machines taken in trade and guarantee that every machine offered has been actually rebuilt by our experts. These machines are priced especially low and will give excellent satisfaction. Write for Bargain List No. 22.

The C. F. Pease Company, 836 N. Franklin St., Chicago

Right hand motion required to draw two 3-inch lines at right angles using T-square, Triangle etc. (Reduced size.)

Right hand motion required to draw two 3-inch lines at right angles using Universal Drafting Machine. (Reduced size.)

Annoying Interruptions Driven from Drawing Boards

CONSIDER the right hand motions and interruptions to draw two 3-inch lines at right angles by using the old-fashioned method.

First, the T-square is put in position on the board, a line drawn, square removed, scale picked up, line measured, scale laid aside, triangle set in position, vertical line drawn, triangle set aside, scale again picked up, vertical line measured, scale put down.

If either line is more than three inches in length, the eraser is brought into play and part of the

above operations repeated.

Contrast this round-about, monotonous method of drawing these two lines with the way it is done by a Universal Drafting Machine. The machine is placed in position and all the right hand does is draw the lines to required lengths as indicated on scale. All accomplished with two operations of the right hand.

You can have a Universal Drafting Machine sent to you for free trial. Write for our new 1923 plan.

Can't be beat for convenience —and results!

No dark room! No special operator! No complicated machine parts to get out of order. Complete automatic control that insures snappy, clear-white-on-dark-blue results. That's how the Wickes System puts your blueprinting on a practical basis.

Your own office boy can be the operator and produce perfect blueprints. Light-tight compartments make it possible to work anywhere. Sharp, mercury vapor lights directed straight at the tracings insures quick printing—a possible speed of 30 in. a minute, 2 to 48 in. wide.

It'll pay you to investigate it at once.

Design, Construction
Operation, Rates
Chemical and Biological Labo-
ratories

Horton, Robert E.

Mem. Inst. C. E. Mem. Am. Soc. C. E.
Consulting Hydraulic Engineer
Reports, Estimates, Design and
Construction for Water Power,
Water Supply, Storage, Flood
Control, Irrigation and Drainage.
Specialist in Hydraulic and Hy-
drologic Problems, Rainfall,
Evaporation, Stream Yield and
Ground Water, Water Power
Valuation.
26 Douth Bldg. Albany, N. Y.
Laboratory, Voorheesville, N. Y.

Hopkins & Field

Chas. C. Hopkins, Arthur M. Field.
Consulting Engineers
Water Supply, Sewerage, Wastes
Disposal, Municipal Engineer-
ing, Expert Testimony, Appraisals.
Rochester, N. Y., 319 Cutler
Building.

Walter Kidde & Company

*Incorporated
Engineers and Constructors*
Business established 1900
Inspections, Industrial Plants,
Reports, Wharves and Piers,
Design, Power Plants,
Construction, Chemical Works.
New York City, 110 Cedar St.

George A. Johnson

Consulting Engineer
Water Supply and Purification,
Sewerage and Sewage Disposal,
Refuse Collection and Disposal,
150 Nassau St., New York.

Landreth, Olin H.

Consulting Engineer
Hydraulic and Sanitary Engi-
neering, Consultation, Inves-
tigation, Valuation.
New York, No. 156 Fifth Ave.

Landreth, Wm. B.

M. Am. Soc. C. E.
Water Supply, Water Power,
Flow of Streams, Reports,
Estimates, Valuation.

Chief Eng. Southern Power Co.
Consulting Engineer
New York City, 311 Fifth Ave.
Charlotte, North Carolina.

McClellan & Junkersfeld Incorporated

Engineering and Construction
45 William St., New York
Chicago Philadelphia

Mead, Daniel W. Scheidenhelm, F. W.

Consulting Engineers
Hydro-electric Developments,
Water Supply, Irrigation, Drain-
age, Flood Control.
New York, 30 Church St.

Meyer, Strong & Jones, Inc.

Power Plants—Mechanical and
Electrical Equipment—Heating
and Ventilating
New York City, 101 Park Ave.

Moran, Maurice & Proctor

Consulting Engineers
Foundations for Buildings,
Bridges and Dams, and all Sub-
structure Work, Investigations,
Reports, Consultations, Designs
and Supervision
New York City, 9 East 15th St.

North, Allison & Ettlinger

Consulting Engineers
City, Surveyors, Topographic
Surveys of large tracts,
City Planning, Field Supervision,
Dock, Terminal Development,
Staten Island, New York, Crab-
tree Bldg.
New York City, 112 E. 19th St.

Potter, Alexander

Consulting Engineer
Hydrants, Sanitation, Concrete
Structures, Tel. 5501 Cortlandt
New York, 50 Church Street.

Potts, Clyde

M. Am. Soc. C. E.
Consulting Sanitary Engineer
Sewerage and Sewage Disposal,
Water Works and Water Supply
Reports, Plans and Estimates
New York, 30 Church St.

Dwight P. Robinson & Company, Inc.

Engineers and Constructors
Industrial Plants, Power De-
velopments, Railroad Shops and
Terminals
New York, 125 East 16th Street
Chicago, Philadelphia, Youngs-
town, Los Angeles, Montreal,
Rio de Janeiro

Robinson, Geo. L.

Consulting Engineer
Sewers, Sewage Disposal, Water Supply.
5621 Grand Central Terminal
New York.

Sanderson & Porter

Engineers

New York, 52 William Street,
Chicago, 72 West Adams Street,
San Francisco, 14 Montgomery St.

Sears, Horace H.

Cons. Engr. and Archt. at Law
M. Am. Soc. C. E.
Municipal Improvements,
Bond Investigations,
Legality of Bond Issues,
Finance.
825 Singer Bldg., N. Y. City.

Seelye, Elwyn E.

Consulting Engineer
Reinforced Concrete
Structural Steel
Foundations
New York 101 Park Avenue

Steinman, Dr. D. B.

M. Am. Soc. C. E.,
M. Am. Ry. Eng. A.
Consulting & Designing Engineer
Bridges and other Structures,
Engineering Projects—Designs,

ports, Valuations, and Advisory
Service.
New York 25 Church St.

Vermeule, Cornelius C.

Consulting & Designing Engineer
Water Supply, Sewerage,
Water & Steam Power Plants,
Reports, Valuations.
New York 38 Park Row

Waddell, Dr. J. A. L.

Consulting Engineer
Steel and Reinforced Concrete
Structures, Waddell's Vertical
Lift Bridge, Difficult Founda-
tions, Reports, Checking of De-
signs, Advisory Service, and
Appraisals.
New York, 35 Nassau Street.

Joseph H. Wallace & Co.

Consulting Industrial Engineer
Industrial and Power Plants,
Hydraulic Developments—In-
vestigations—Consultation—
Reports.
New York City. Toronto.

Wells, James P.

Consulting Hydraulic Engineer
Water Supply, Water Power,
Storage Reservoirs
Cutler Bldg., Rochester, N. Y.

The J. G. White**Engineering Corporation**

Engineers—Constructors

Industrial Plants, Buildings,
Steam Power Plants, Water
Power, Gas Plants, Steam and
Petroleum Railroads, Transmission
Systems.

New York 13 Exchange Place

Wigley, C. G.

M. Am. Soc. C. E.
Consulting Sanitary Engineer
Formerly Chief Engr. N. Jersey
State Dept. of Health, Sewerage
& Water Works, Reports, De-
signs, Construction, Appraisals
New York, 2 East 23rd St.

Penna. & Ohio**Albright & Mebus**

Civil and Sanitary Engineer
Sewerage, Sewage Disposal,
Town Planning.
Phila., Pa., 1502 Locust St.

Bean, George L.

Consulting Engineer
Water Supply, Water Works
Sewers, Highways.
Reports, Designs, Appraisals
Phila., Pa., 201 N. Broad St.

The J. N. Chester Engrs.

Engineers*
L. C. Mechling, E. L. Zearley.
Coal, Coke Plants.
Uniontown, Pa.

Franklin & Company

Consulting Engineers
Water Supply, Sewage Disposal,
Town Planning,
Report-Valuation Design.
Philadelphia, 906-7 Crozer Bldg.

**Gannett, Seelye &
Fleming Engineers**

Reports - Valuations - Design
Management - Municipalities,
Utilities - Industrials
Eric Pa. - Harrisburg, Pa.
Memphis Tenn.

Gascoigne, George B.

Consulting Sanitary Engineer
Sewerage and Sewage Disposal,
Water Supply and Purification
Treatment of Industrial Waste.
Cleveland, Leader-News Bldg.

**Harrison Mertz &
Emlen, Inc.**

Engineering and Consulting
Sewage Disposal, Water Supply,
Landscape Contracting.
Franklin Bank Building,
Philadelphia, Pa.

Morris Knowles, Inc.

Specializing in Municipal En-
gineering and Public Utilities.
Real Estate Developments and
Town Planning.
Pittsburgh Cleveland

Ledoux, J. W.

Consulting Engineer
Water Works, Water Power,
Power Plants, Reports, De-
signs, Construction Supervision,
Valuation, Arbitration, Rate
Schedules.
Phila. Pa. 112 North Broad St.

Miller, H. B.

Mining Engineer & Geologist
Coal land examinations and re-
ports. Properties prospected,
Surveys and Maps of all kinds.
Over twenty years' experience,
Penna., Ohio, W. Va. and Ky.
Oliver Bldg., Pittsburgh, Pa.

W. E. Moore & Co.

Engineers
Reports, Designs and Supervision
of Public Service Properties,
Industrial Plant Installations,
Electric Furnace Design and
Applications.
Pittsburgh, Pa., Union Bank Bldg.

Quimby, Henry H.

Consulting Engineer
Bridges, Foundations.
Philadelphia, 3920 Girard Ave.

Scotfield Engineering Co.

*Consulting, Designing, Supervising
Engineers*
Philadelphia Pennsylvania

**The U. G. I. Contracting
Co.**

Engineers and Constructors

Hydro-Electric and Steam Power
Plants, Utility Surveys, Ap-
praisals and Rate Structure,
Coal Gas, Water Gas and Pro-
ducer Gas Plants.

Broad and Arch Sts., Phila., Pa.

**Watson Engineering
Company, The**

*Designing and Construction
Engineers*

Industrial and Power Plant and
Equipment, Bridges and Rail-
way Buildings, Docks, Terminals
and Marine Structures.

Warehouses and Commercial
Buildings, Installation and
Engineering Reports.
Cleveland 4614 Prospect Ave.

Schools & Colleges

College of Engineering

Northwestern University
Five years of broad, thorough training, small classes in which each student receives individual attention from head professors. Unsurpassed opportunities to see engineering projects and meet engineers.
A young thriving College in an old University.
Write for "Best Preparation for Engineering" and "Booklet of Views."
John F. Hayford, Director
Evanston, Ill., Swift Hall

Lafayette College

Technical Courses in Chemical, Civil, Electrical, Mechanical and Mining Engineering. Write for illustrated catalogue to the Registrar, Easton, Pa.

College of Engineering

Courses in Civil, Mechanical, Electrical, Sanitary, Municipal, Chemical Engineering. Short course in Structural Drafting.

Enter any time. No matriculation or registration fees. Expenses 1 to 1.5 less than at other first-class schools. School year—Four quarters of 12 weeks each.

Length of Courses 120 Weeks. Save one year and \$1000.

Experienced Instructors. Splendid Laboratories.

For catalog, bulletins or information address: Albert Edwin Smith, President, Ohio Northern University, Ada, Ohio.

Clarkson College of Technology

Courses leading to the degrees of Bachelor of Science in Chemical, Civil, Electrical and Mechanical Engineering.

Catalog upon application.

Potsdam, N. Y.

New York University College of Engineering

Civil, Mechanical, Chemical and Industrial Engineering
For information address Chas. Henry Snow, Dean
University Heights, New York.

Norwich University

(Founded 1819)

The Military College of Vermont, Academic Courses in Civil and Electrical Engineering. Address Prof. H. B. Roberts.

Northfield, Vermont.

Inspecting & Testing

Electrical Testing Laboratories

Electrical, Photometrical and Physical Tests, Inspection and Tests of Electrical and Engineering Materials. Main Office and Laboratories, New York, 80th St. and East End Ave.

Robert W. Hunt Co.

Bureau of Inspection, Tests and Consultation
Chicago, New York, Pittsburgh, St. Louis, San Francisco, Seattle, Montreal, London.

Bingham Street Bridge, Reading, Pa., crossing the Schuylkill
Designed by C. F. Sanders, County Engineer, Berks County, Pa.

Bridge at Olympia, Wash. Elastite Expansion Joint used.

Protecting great bridges against temperature

TEMPERATURE fluctuation, and the consequent expanding and contracting of these great concrete masses, are rendered harmless to the durability of big bridges and viaducts by the installation of Elastite Expansion Joint at regular intervals.

The fact that Elastite Expansion Joint, "the sandwich joint," is handled as a slab, in any dimension and thickness, makes installation comparatively simple and easy. It is the practical joint used exclusively by practical engineers and contractors. It is easily cut to shape with an old saw, or can be supplied cut to exact fit to meet your requirements.

When you need "joint," remember that there are big stocks of Elastite Expansion Joint in seventeen cities. Your order will be immediately shipped to your job from the nearest point. Send for sample and all the facts.

THE PHILIP CAREY COMPANY

18 Wayne Ave., Lockland, Cincinnati, Ohio

**Carey
Elastite**
TRADE MARK U.S. PAT. OFFICE
**EXPANSION
JOINT
PROVED AND
ACCEPTED**

Carey Elastite Expansion Joint is an asphaltic body, formed of a high-grade asphaltic compound carefully refined and tempered, sandwiched between two walls of asphalt-saturated felt forming an elastic, compressible joint. It is made in lengths, widths and thicknesses as required, can be cut to crown or to any special shape and comes to the job ready to use.

*Carey Elastite Expansion Joint
is used in these bridges and
viaducts*

“Have used all makes of locomotives for 20 years and the Vulcan is far superior”

This statement was made by Mr. E. S. Guth, Superintendent for the Security Cement & Lime Company of Hagerstown, Md. This company has had three Vulcan Locomotives in use since 1918.

“The repairs and upkeep of these locomotives,” adds Mr. Guth, “are very low. They have good lasting qualities and stand up well under hard usage.”

He also states that the parts are easily accessible and that our service is very good.

This is a fine example of the kind of enthusiasm we hear from Vulcan users in all parts of the country.

The Vulcan shown in the photo is the 12x16-in. cylinder, standard gauge, four-coupled saddle tank type, weighing 25 tons.

Each of the three Vulcans used by this Company travel approximately 46 miles a day, hauling 8 cars a trip, each car weighing 1½ tons loaded. The steepest grade is about 3%.

We'll be glad to tell you all about the advantages of the Vulcan as well as send you a long list of users.

**ALL TYPES AND SIZES**

The Compressor shown here is the E-4 Type. It is a motor-driven unit with piston displacement of 110 cu. ft. per minute. This is but one of many Westinghouse-National types, which are built in all sizes from 11 to over 600 cu. ft. capacity. Write for the Westinghouse-National catalog.

AIR COMPRESSORS FOR EVERY USE

WESTINGHOUSE-NATIONAL Air Compressors meet every requirement of compressor service in a field represented by a size range of 11 to over 600 cubic-feet output of air per minute.

In addition to exceptionally high-grade construction, Westinghouse-National models are equipped with the famous HP Automatic Control, which effects an economy in the use of power and also eliminates needless wear and depreciation on the machine as a whole.

This special type of control is an exclusive feature, found only on Westinghouse-National Compressors.

Westinghouse Traction Brake Company
General Office and Works: Wilmerding, Pa.

WESTINGHOUSE-NATIONAL *Air Compressors* "QUALITY MACHINES FOR QUALITY SERVICE"
